HEARING ON THE PROPOSAL BY THE MINISTRY OF NATURAL
RESOURCES FOR A CLASS ENVIRONMENTAL ASSESSMENT FOR
TIMBER MANAGEMENT ON CROWN LANDS IN ONTARIO

IN THE MATTER of the Environmental
Assessment Act, R.S.O. 1980, c.140;

- and -

IN THE MATTER of the Class Environmental
Assessment for Timber Management on Crown
Lands in Ontario;

- and -

IN THE MATTER of an Order-in-Council
(O.C. 2449/87) authorizing the
Environmental Assessment Board to
administer a funding program, in
connection with the environmental
assessment hearing with respect to the
Timber Management Class
Environmental Assessment, and to
distribute funds to qualified
participants.

Hearing held at the Ramada Prince Arthur
Hotel, 17 North Cumberland St., Thunder
Bay, Ontario, on Tuesday, March 7th,
1989, commencing at 9:00 a.m.

1 ---Upon commencing at 9:00 a.m.

2 THE CHAIRMAN: Good morning, ladies and
3 gentlemen. Be seated, please.

4 Ladies and gentlemen, the Board would
5 like to announce a slight schedule change, and that is
6 for the day April 3rd, something has come up that will
7 mean that the Board will not be able to sit that day.

8 We are suggesting that that week we sit
9 Tuesday through Friday instead of Monday through
10 Thursday, and we would commence on Tuesday at one and
11 leave on Friday at the normal time.

12 Are you ready, Mr. Freidin?

13 MR. FREIDIN: Yes.

14 DAVID LOWELL EULER,
15 PETER PHILLIP HYNARD,
16 JOHN TRUMAN ALLIN,
17 RICHARD BRUCE GREENWOOD,
CAMERON D. CLARK,
GORDON C. OLDFORD, Resumed

18 CONTINUED DIRECT EXAMINATION BY MR. FREIDIN:

19 Q. Mr. Greenwood, could you advise the
20 Board of the subject matters that you are going to deal
21 with in your evidence today?

22 MR. GREENWOOD: A. Yes. What I would
23 like to do is build upon the evidence given in Panel 9
24 which dealt primarily with principles at play --
25 particularly at play with change within the forest but

1 relate those to the specific practices of harvest.

2 And to do that, I have organized
3 potential effects into five areas. Rutting and
4 compaction is the first area, erosion, micro-climate,
5 insect and disease control, and forest diversity.

6 Q. Rutting and compaction, erosion,
7 micro-climate...?

8 A. Insect and disease control. The last
9 one is forest diversity.

10 THE CHAIRMAN: Do you have a page number
11 for your paper in the witness statement?

12 MR. GREENWOOD: Yes, I do. The document
13 starts on page 205.

14 THE CHAIRMAN: Thank you.

15 MR. FREIDIN: Q. Now, Mr. Greenwood,
16 could you advise the Board how you intend to approach
17 the subject matters that you have just referred to?

18 MR. GREENWOOD: A. What I would like to
19 do is discuss each of those topics individually and
20 then I would like to follow up after that evidence has
21 been led by illustrating some of the points visually
22 with slides.

23 Q. Mr. Greenwood, the first topic then
24 of compaction and rutting, could you advise the Board
25 what compaction of the soil is and what rutting of the

1 soil is?

2 A. I find when you are discussing this
3 topic it is easiest if you visualize the soil as a
4 combination of rigid particles and air spaces. And for
5 purposes of study, those air spaces are grouped into
6 two sizes; the large size is called macro-pores and the
7 smaller size which is defined as micro-pores.

8 And compaction is simply pressure which
9 is exerted on the soil which forces those rigid
10 particles into the larger spaces, the macro-pores, and
11 in doing so it reduces the macro-porosity of the soil
12 but increases the micro-porosity of the soil, so the
13 number of micro-pores is increased.

14 Rutting is simply downward pressure that
15 exceeds the ability of that soil to hold together. The
16 friction which is holding the particles together is
17 exceeded, the soil fails or shears and, therefore, you
18 get a depression forming. Rutting really is just
19 compaction of the soil on the bottom and sides of a
20 depression.

21 Q. How does pressure occur which can
22 have this effect?

23 A. I think Mr. Armson spoke to this
24 briefly. It comes as a result in harvest of travel of
25 heavy equipment and is particularly the case where that

1 equipment travels repeatedly over the same ground.

2 Q. Is the potential for these direct
3 effects of harvest the same everywhere?

4 A. No, it is not.

5 Q. And could you explain why the
6 potential is not the same everywhere?

7 A. We have heard in previous panels
8 about the great site variability that is within the
9 area of the undertaking and that is at play here as
10 well. When looking at site factors there is really
11 three that come into play.

12 Q. And --

13 A. I am sorry?

14 Q. I'mm sorry.

15 A. The first one is the soil
16 characteristics and of particular pertinence here is
17 soil texture and soil moisture in that finer textures
18 already have fewer macro-pores and, therefore, if the
19 number of macro-pores which are there are reduced it
20 can have a more severe effect.

21 The moisture plays a role in that -- you
22 can almost look at it as lubrication. If these rigid
23 particles have to move and there is moisture there,
24 they are able to move easier into those macro-pores
25 and, therefore, compaction or in the case of the

1 failure from rutting can take place easier.

2 Now, there is some interaction between
3 those soil characteristics in that the soil moisture
4 which could be held in the soil is related to texture.
5 If you have a coarse texture then it is usually fairly
6 rapidly drained, the water moving into it moves through
7 and out and, therefore, the moisture content that would
8 be required to increase its susceptibility for rutting
9 and compaction just doesn't take place.

10 Q. All right. And what we are
11 describing here are the site factors which determine
12 susceptibility to compaction and rutting; is that
13 correct?

14 A. That's correct.

15 Q. Okay. So we have dealt with texture
16 and moisture as being two of those.

17 A. Yes, the first factor is really soil
18 characteristics of which the two important factors
19 would be texture and moisture.

20 Q. All right. And what would the second
21 site factor be?

22 A. Well, there is a certain degree of
23 protection of that mineral soil which is in the forest
24 in the form of the ground vegetation and the root
25 network. And when equipment is operating with heavy

1 ground vegetation, that ground vegetation can in fact
2 increase the flotation of the equipment and, therefore,
3 reduce its ability to impact on the soil.

4 The same is true of the root network. If
5 you have a strong root network at the top of the
6 mineral soil it can also increase the flotation of that
7 equipment and, therefore, reduce its effect on the
8 mineral soil.

9 The third effect would be the forest
10 floor -- or sorry, the third factor, the organic matter
11 as was described in detail by Mr. Armson. It also can
12 work somewhat as a cushion and protect the mineral
13 soil. It also can play a role if it, through
14 weathering, has been incorporated into the mineral
15 soil -- at the top of the mineral soil in that organic
16 matter can increase the porosity of the soil and,
17 therefore, it can increase the number of macro-pores
18 within the soil and make it less susceptible.

19 The second major factor, other than site
20 factors, is obviously season. In terms of
21 susceptibility, in winter where ground is frozen, the
22 soil is just not susceptible to rutting or compaction.
23 In the summer, some sites are not susceptible by nature
24 of the soil characteristics and the protection, the
25 factors that I gave a minute ago of site.

1 Others are always susceptible because
2 moisture is high or the texture of the soil is so fine
3 that in fact macro-porosity is low. And there are
4 still others which would be susceptible under certain
5 conditions, for instance, after rainstorms where the
6 moisture is in fact higher in the soil.

7 Q. And just going back to the site
8 factors, when you were talking about soil protection
9 you talked about ground vegetation and the root
10 network. I think you said that those would give some
11 flotation to the equipment?

12 A. That's correct.

13 Q. And when you dealt with the soil
14 organic matter, you spoke about -- it can in fact cause
15 the soil to be like a cushion?

16 A. Correct.

17 Q. When you are talking about this
18 cushion and you are talking about flotation, are you
19 talking about the same thing?

20 A. Not exactly. When the equipment runs
21 over the vegetation it, of course, is bending over and
22 that spring can in fact lift the equipment off the
23 ground.

24 When I was referring to the organic
25 matter acting as a cushion, I was thinking of it more

1 as a sponge. It is an area that is full of air spaces
2 and if it is thick enough it can absorb some of the
3 shock without putting pressure on the mineral soil
4 underneath it.

5 Q. Okay, thank you. During the
6 evidence, and I think particularly during the evidence
7 of this panel, and we have heard a lot about the
8 special nature of the Clay Belt.

9 And could you advise: Do the different
10 characteristics of the Clay Belt play any role in terms
11 of susceptibility to compaction and rutting?

12 A. Yes, they do. It is not so much the
13 different characteristics of the Clay Belt. The
14 characteristics of the Clay Belt; that is, the site
15 types that are there, do exist in other places within
16 the area of the undertaking.

17 I think the significance of it is that it
18 is the prevalence of those site types which are
19 susceptible to compaction and rutting within the Clay
20 Belt. Those site types are usually rather limited in
21 other parts of the area of the undertaking where the
22 site types are extensive within the Clay Belt.

23 I am really referring to the two main
24 site types which exist in the Clay Belt. Within that
25 area foresters tend to define them as uplands and

1 lowlands, but an upland in the Clay Belt can be as a
2 small a 50 centimetre or metre difference, and that
3 change within this area could put you on to a clay --
4 an upland clay which wouldn't have moisture right at
5 the surface but, being a finer textured soil, would in
6 fact be more susceptible to compaction and rutting when
7 it is not dry.

8 And clays, of course, have greater
9 ability to hold water because of the finer texture, so
10 it is possible that they are not dry even within the
11 summer period. That would make these sites susceptible
12 also to rutting if in fact moisture reaches the point
13 where that can take place.

14 The lowland areas are areas which are
15 depressed and usually have the water table fairly close
16 to the surface and, as such, have developed organic
17 soils or organic layers that are quite deep and organic
18 layers are susceptible to rutting, particularly when
19 the moisture is near the surface.

20 Q. What are the adverse effects of
21 compaction and rutting if they do occur?

22 A. There is two main effects. The first
23 one is reduced permeability to oxygen or to air and
24 that can, in fact, affect site productivity. The
25 second one is it can create difficulties for renewing

1 the site.

2 Q. Can you explain how those
3 activities -- or those effects would cause difficulties
4 in renewing a site?

5 A. Well, aeration or oxygen within the
6 soil is important in more than one way. Good aeration
7 can favour the water, oxygen and nutrient absorption by
8 the roots and, of course, if the roots aren't absorbing
9 large amounts of these then that can affect growth.

10 And I think anybody that has a garden or
11 house plants knows this. When the watering starts to
12 compact the surface you usually go in and till up the
13 soil and what, in fact, you are doing is increasing the
14 aeration within the soil and that can affect
15 productivity.

16 The amount of oxygen in the soil can also
17 affect organisms which require oxygen to live and the
18 ones that we are particularly concerned about here are
19 those which decompose the organic matter, the aerobic -
20 they are called aerobic organisms can be reduced if
21 oxygen in the soil is reduced and, therefore,
22 decomposition would not take place. And that is
23 important in releasing the nutrients and in turn can
24 affect growth.

25 Another factor that is affected by

1 aeration is the ability of water to move through the
2 soil. If in fact you reduce those macro-pores, the
3 water cannot move through the soil as quickly and, in
4 fact, surface water could run over the surface as
5 opposed to infiltrating into the soil.

6 In terms of the second main area,
7 renewal, when you compact that soil you are increasing
8 the strength of the soil and that can lead to the
9 reduced ability of roots to penetrate the soil and
10 that, of course, then can limit root size and growth.
11 It can also have an effect, this increased strength, in
12 reducing the ability of a seedling to establish.

13 If in fact the root can't get a footing
14 in this soil, or if it is a planted tree and they can't
15 regenerate and grow, then you can have less survival of
16 those seedlings or those seedlings have less access to
17 nutrients and, therefore, growth rate can be declined
18 or reduced.

19 If in fact the rutting created the
20 condition where water could not infiltrate into the
21 site, you can get large areas of ponding on a site
22 which obviously reduces the area, the micro-site which
23 can be either planted or seeded or on which natural
24 regeneration can take place.

25 Q. Does current timber management

1 practice address the potential for the effects that you
2 have described, Mr. Greenwood?

3 A. Yes, they do. And in terms of some
4 of the definitions that were given by Mr. Clark, they
5 particularly take actions to prevent or minimize both
6 these effects.

7 Q. And what are the actions that are
8 taken in order to prevent or minimize these potential
9 effects of compaction and rutting?

10 A. I think Mr. Oldford spoke to the
11 first one that I would like to speak to in some detail
12 and that is modification of equipment. In fact, I
13 think that was even shown in some of the slides that he
14 referred to.

15 This is quite prevalent in the Clay Belt
16 where susceptibility is high. Within the Clay Belt
17 traditionally the areas were harvested in winter, this
18 was when harvest, throughout the whole area of the
19 undertaking, was in fact a winter operation which was
20 based on river driving in the spring, you had to have
21 the logs on to the water in the spring. Throughout
22 this period of time there was, of course, no effect
23 with the ground being frozen and using horses.

24 With the advent of mechanized harvesting
25 in the 50s and 60s, it became important from an

1 economic sense to keep that equipment working year
2 round and particularly in the 60s there were
3 attempts -- 60s and 70s to keep that equipment
4 operating in the summer season. Those attempts
5 resulted in rutting, particularly, and reduced ability
6 to renew the site and developments took place then
7 which led towards these high flotation or wide tires
8 and with that development the equipment was able to
9 work year round without creating the rutting. As well,
10 wide tracks would be modification of equipment as
11 opposed to narrow tracks which allows that equipment to
12 work year round.

13 A second action that could be taken would
14 still be to modify the time of year of operation. This
15 is particularly an action that can be taken outside the
16 Clay Belt where susceptible sites are not as prevalent,
17 in fact are rather small in area. It is normal
18 practice that in these areas when the sites are
19 encountered they are set aside and harvested in winter.

20 Q. These are the sites which are
21 susceptible to these effects?

22 A. That's correct. The use of
23 modification of equipment is particularly prevalent
24 within the Clay Belt because of their inability to move
25 to other sites which aren't susceptible.

1 A third area would be to modify the skid
2 trail patterns within an area that is susceptible. If
3 you have modified the equipment so that it can operate
4 within that area, you can minimize any effects even
5 further by modifying the pattern with which that
6 equipment operates.

7 Mr. Armson -- or Mr. Oldford referred to
8 the Ardco, he drew a picture of it the other day, which
9 is a forwarder which can carry three times the load of
10 a normal skidder and by doing so limits the travel
11 across an area. Where the skidder would have to make
12 repeated trips to the roadside, this machine would only
13 make a trip one in three times compared to a skidder.

14 Those would be three areas that -- or
15 actions which could be taken to minimize or prevent
16 compaction and rutting.

17 A third area that is again particularly
18 prevalent in the susceptible area within the Clay Belt
19 is training of equipment operators, particularly
20 training to recognize sensitivity to compaction and
21 rutting. It is obviously the operator who is in charge
22 of that machine that can have the largest impact once
23 they are on a site and the minimization. And I have
24 some slides later that I think will demonstrate this
25 point a little better.

1 Q. In terms of modifying skid trail
2 patterns, the example you gave was one where you use a
3 different piece of equipment and, therefore, didn't
4 have as many trips from the -- sort of from the
5 cut-over area to the roadside.

6 If you are using skidders and you are --
7 to get the trees to roadside and you find out that you
8 have an area which is susceptible if you continually go
9 over the same area, can you modify your skid trail
10 patterns using the same equipment, though?

11 A. Yes, you would -- even with the use
12 of high flotation equipment, you would still limit the
13 use of that equipment to specific areas so that, in
14 fact, if there is slight disturbance it is restricted
15 to a small proportion of the area.

16 Q. Does rutting or compaction still
17 occur, Mr. Greenwood?

18 A. Yes, it does, to a limited extent.

19 Q. And are you able to indicate where it
20 occurs to a limited extent or why -- and why it still
21 occurs?

22 A. When I was describing site factors,
23 one of the sites that I described was those sites which
24 are only susceptible under some conditions. And it
25 does happen where a site has equipment on it and has

1 not been susceptible, but due to a change such as a
2 weather pattern, rain for two or three days, the site
3 could become susceptible and in the process of this
4 sometimes equipment is still operating and can in fact
5 create a minor amount of rutting, particularly.

6 There are also sites which overall are
7 not susceptible, but in very small patches or places
8 may be susceptible; that is, there may be a wet spot
9 within the site of a smaller area and if the equipment
10 was to move through that site it could in fact create
11 rutting within that particular portion of the site.

12 Q. You indicated that if you were on one
13 of these sites where weather conditions changed and
14 operations continued you may get a minor amount of
15 rutting. Could you perhaps give the Board some idea of
16 what you mean when you say a minor amount of rutting?

17 A. Well, the rutting that I have seen
18 under those circumstances, again, would be the small
19 patches, like wet patches. Sometimes those are only
20 the size of a skidder and normally operators would try
21 and avoid these.

22 Obviously if they are sitting in a wet
23 pocket they aren't being very productive. So, again,
24 it would be part of normal operations to avoid these.

25 It could also be where the rain is

1 starting to fall and wheels are starting to slip on
2 hillsides, things like that. So it would normally be
3 restricted to where the equipment is travelling and in
4 isolated patches of where that equipment is passing.

5 Q. Okay. In our opinion, would the
6 rutting or compaction which does occur from time to
7 time, as you have described it, does the kind of
8 rutting or compaction that you are speaking of result
9 in a significant reduction in productivity of the site?

10 A. In the case of compaction, I am not
11 aware of any measured losses in productivity except
12 possibly where roads and landings have been regenerated
13 and there has been compaction on those roads and
14 landings.

15 When you consider rutting, with the
16 modification of operations and the actions taken to
17 prevent and minimize, the occurrence is really low and
18 is limited to a number of the susceptible sites -- site
19 types, or actually the number of susceptible site types
20 is limited is really what I am saying.

21 The duration of that susceptibility on
22 those sites, particularly those which change the
23 susceptibility, is usually relatively short. If it is
24 a weather pattern, it dries out almost as quickly
25 usually as it became susceptible, and during that

1 period of time equipment operators may in fact be able
2 to move to another portion of the site or an adjoining
3 site and not create any effect.

4 So overall the areas of rutting are small
5 and isolated and generally wouldn't affect productivity
6 to any significant effect on a site.

7 Q. And, again, could you put in general
8 terms some sort of dimensions on what you refer to as
9 an isolated patch or a small patch of susceptible
10 ground?

11 A. Maybe the best way would be just to
12 give an example. I have mentioned that this occurrence
13 is generally restricted to where the equipment is
14 operated in a repeated fashion.

15 The example that I have in my mind would
16 be where equipment has been operating on a site which
17 has not been susceptible and increase in moisture
18 through precipitation has made it susceptible and there
19 may be a slight slope, 10 or 15-foot slope that the
20 equipment is having to operate up and down a short
21 slope within the site.

22 If the equipment operates on that slope
23 repeatedly, it may in fact -- the moisture may cause
24 wheel slippage just the duration of that slope which
25 could in fact cause ruts or compaction on that slope.

1 So it may be an instance where it is only 10 to 15 feet
2 long where the equipment is trying to get up a slope.

3 If it was in fact a long slope -- the
4 grading of our slopes in Ontario are such that you
5 normally wouldn't get that type of slippage over the
6 long distance, and if it was that steep the equipment
7 wouldn't be able to operate on it.

8 Q. Okay, thank you. How does a forester
9 determine whether the sites that are to be harvested
10 are ones which are susceptible to compaction and
11 rutting, and also how would they determine or assess
12 the degree of susceptibility of compaction and rutting
13 if in fact they thought that it was going to be
14 susceptible?

15 A. Well, the ones that you would
16 normally key in on are the those soil characteristics
17 and they can in fact be measured either directly or
18 indirectly; directly through field observation or the
19 results of field observation, or indirectly through
20 interpretation of the vegetation which in fact reflects
21 soil texture and soil moisture.

22 Q. When we deal with directly
23 determining those factors, I think it was maybe Mr.
24 Armson that indicated that on occasion the forester
25 might get out there on the site and kick the duff. And

1 could tell certain things about the soil
2 characteristics from doing that? Do practising
3 foresters do more than just kick the duff on occasion?

4 A. I've got to admit I have kicked the
5 duff and I have got boots to show it, I guess, but I
6 carry a shovel with me and I think a lot of foresters
7 did. I think I heard Mr. Hynard say the other day he
8 did the same thing.

9 And if in fact I was concerned about the
10 soil characteristics on the site and had the
11 opportunity to measure it directly, I would go into the
12 site with a shovel and in fact dig a soil pit and take
13 a look at what the soils were.

14 Q. Now, you indicated that you could
15 determine some of these factors, and particularly soil
16 characteristics indirectly. And could you perhaps
17 expand on how you are able to -- or foresters are able
18 to make those types of determinations about soil
19 characteristics indirectly?

20 A. Well, I think I mentioned a minute
21 ago that if you were determining them indirectly you
22 would be interpreting the vegetation as it reflects the
23 characteristics of site which in fact make the site
24 susceptible, and there is more than one way of doing
25 that.

1 The first way, and the way which is most
2 common in the Clay Belt area and in fact came about as
3 a result of some of the susceptibility in the Clay Belt
4 area, is the forest eco-system classification system.
5 This is a formalized use of vegetation as an indicator
6 of the site and, in fact, of the site factors of
7 moisture and soils.

8 Q. Now --

9 A. Sorry?

10 Q. I was going to ask you, that if a
11 forester doesn't have this formalized document, this
12 forest eco-system classification which gives him this
13 relationship, are they able to make an assessment of
14 the soil characteristics through observations of the
15 vegetation on the site?

16 A. Very much so. Part of the formal
17 training and in fact part of the experience a forester
18 gains is in doing just that, it is interpreting
19 vegetation as it relates to site for more than one
20 reason.

21 When you go into the existing forest it
22 gives you an indication of what's there and sometimes
23 you are trying figure out why it is there. So you are
24 constantly examining these relationship, particularly
25 because it has importance when you are dealing with the

1 renewal program.

2 If you don't understand the relationships
3 between site and vegetation you will have a difficult
4 time making prescriptions, the best prescription for
5 that site. So these relationships are something that
6 are taught in a normal sense and, in fact, are more
7 refined as that forester becomes more experienced,
8 particularly on their local area where they get to know
9 the relationships quite well.

10 In terms of the FEC, many of the
11 relationships which are embodied in a formal way in the
12 FEC came from the knowledge of foresters who understood
13 those relationships. I guess the significant
14 difference is that each forester tends to create a
15 model in their mind of those relationships and they may
16 not always be able to communicate that model
17 effectively.

18 I may be talking about a jack pine site
19 with Labrador T and have a very definite site in my
20 mind, when a fellow forester might also be thinking of
21 jack pine and Labrador T but have a little different
22 site in mind. By formalizing those relationships in
23 something like a FEC, you are able to communicate and,
24 therefore, pass knowledge better.

25 I mentioned the FEC first, being the

1 formalized system. There are -- this knowledge of
2 relationships then allows the forester to interpret
3 the vegetation from other sources of information and
4 the key one that I am thinking of here is aerial
5 photos.

6 If you understand how canopy vegetation
7 relates to soils and moisture, you can in fact
8 interpret susceptibility of the site to various things
9 patching and rutting, erosion and with that knowledge
10 and ability of interpreting the canopy vegetation you
11 can in fact interpret the site from flyovers as well.

12 And I guess the big advantage of a
13 flyover as opposed to aerial photos is that you can get
14 closer to the ground and get an indication of the
15 ground vegetation which would allow you to refine your
16 interpretation even further still.

17 Those would be three ways of indirect
18 that in fact exist in the area of the undertaking now.

19 Q. How much can you actually tell from
20 the indirect methods of aerial photographs from flying
21 over an area?

22 A. That would depend to some extent on
23 this experience that I spoke about. The basics are
24 there, as soon as you go to the field jack pine doesn't
25 normally grow in very wet sites, black spruce can, so

1 that the broad basics are in fact understood, but as
2 you get to know your particular area you can in fact
3 reduce the number of relationships that you are having
4 to interpret.

5 For instance, there are some management
6 units which have no clay on them at all, so that an
7 understanding of the relationships between vegetation
8 and clay would not be required by that forester.

9 If in fact the unit is fairly coarse
10 materials that forester through experience may gain a
11 better understanding in interpreting to a refined -- a
12 more refined level the coarser types. So experience
13 and the terrain would both play a part and I think you
14 can tell a lot from these actually.

15 Q. Okay. You gave sort of one example
16 of how you might make -- go into a stand, as you
17 indicated you might -- a jack pine stand and there was
18 Labrador T I think you said.

19 A. Mm-hmm.

20 Q. And that would mean something to a
21 forester, he could come to some conclusions about the
22 site based on those observations?

23 A. That's correct.

24 Q. Can you sort of perhaps expand on
25 that one and give a couple of other examples of how a

1 forester, by making observations within a stand, can in
2 fact come to reasonable conclusions about the
3 characteristics of the soil in the stand?

4 A. If I understand you correctly you
5 would like me to explain what a forester would look at
6 going into a stand to determine some of these
7 relationships other than the vegetation, other...

8 Q. Well, I am concerned about a
9 forester's ability to come to sort of conclusion as to
10 what the soil characteristics are.

11 As I understood your evidence you
12 indicated that when you go into a site that there is --
13 and you see certain vegetation, there is a relationship
14 between the vegetation you see and the type of soil
15 that one could reasonably expect in that situation.

16 A. Yes.

17 Q. And I just would like maybe two or
18 three sort of real life examples--

19 A. Sure.

20 Q. --of where you might do this?

21 A. I keyed in on the vegetation - I
22 think I understand - I keyed in on the vegetation
23 because I think that tends to be the focus of what we
24 are looking at, but there are a number of other factors
25 that would be utilized by a forester or a forest

1 manager in determining that.

2 If I could go back to the aerial photo
3 example. Land form, the geological land form that the
4 vegetation is on is very important in determining the
5 characteristics of soil. You can in fact interpret
6 glacio-fluvial deposits, that is waterlain deposits -
7 I think Mr. Armson defined those in Panel 9 - and
8 those, the waterlain deposits tend to be the coarser
9 deposits, the sands and the gravels, and there are a
10 number of cues that you could pick up on in aerial
11 photographs that would tell you that you are in a
12 glacio-fluvial deposit.

13 That would be quite different, for
14 instance, when compared to a lacustrine deposit which
15 is in fact a deposit which has been waterlain as well
16 but by standing water. It is in fact lake bottoms and
17 that is where you would find your clays and your
18 deposits. So land form would be an important
19 characteristic.

20 And, in fact, even without photographs,
21 driving down a road you would get flags or cues that
22 would give you an idea of what land form that you are
23 on and before you even see the vegetation or get in and
24 check the ground vegetation, you would have an idea of
25 what the soil is.

1 There is other cues that would zero in on
2 this land form. If in fact there were large angular
3 boulders throughout the whole area. Large boulders,
4 particularly strewn across an area, are not waterlain,
5 they are generally dumped by the ice as it was melting
6 and, therefore, you would have an indication -- a good
7 flag, a flag you could even see on photographs if the
8 boulders are big enough that would tell you you are on
9 a till deposit and that till deposit would be mixed
10 types of soils. It would be fines and coarse material
11 and rock fragments within it. And those types of soils
12 would in fact be dry most of the time, but depending on
13 the fines content, the fine-texture content, could be
14 susceptible under certain conditions.

15 So land form and cues of land form become
16 very important.

17 Q. All right. That is land form. And
18 in terms of vegetation, can we go back to that and
19 could you give me an example or two of how you would
20 interpret or come to certain conclusions about
21 vegetation or how are you able to look at the
22 vegetation and have some idea of the kind of soil
23 characteristics?

24 A. Well, the relationship as I mentioned
25 is directly to texture and moisture. Maybe again I

1 should just give some specific examples.

2 If I had jack pine and through ground
3 observation or observation on an aerial photograph I
4 determined that I was on very flat topography, I could
5 in fact determine that amount of glacio-fluvial
6 topography with jack pine, those would be two cues that
7 would tell me I am on a fairly dry site,
8 coarse-textured site and a site that wasn't
9 particularly susceptible to compaction or rutting
10 because of the coarse nature of the site.

11 If I was able to get an indication of
12 ground vegetation, I could refine that even more. If
13 in fact the ground vegetation was strictly lichen, I am
14 on a very, very dry site, no undergrowth, that would be
15 a far drier site than the Labrador T site that you
16 referred to and which would be drier again than a site
17 that had herbs underneath the jack pine, herbacious
18 growth. So you can refine it further depending on the
19 level of information you have.

20 If in fact the overstorey vegetation was
21 a mixture of jack pine and poplar, I would have a cue
22 that I am probably on a more moist site, a fresher site
23 just by that overstorey and I could confirm that again
24 by looking topography, if it was underlaying
25 topography, if it was in fact strewn with boulders I

1 may be on a till deposit. I have got a finer texture
2 in that soil and that could also be reflected in the
3 ground vegetation.

4 The third one would be an area that is
5 depressed; it is flat, it is lowest in topography, it
6 has pure black spruce on it, I have a pretty good
7 indication that such a site would or could possibly be
8 an organic site, high water table and, therefore, would
9 be susceptible to compaction and rutting.

10 Q. Okay, thank you. Now, there was some
11 discussion the other day I guess through Mr. Oldford
12 about different soils and the importance of the
13 operators in terms of ensuring that compaction and
14 rutting doesn't occur.

15 Have you been able to -- well, is any
16 information available for operators, that you are aware
17 of, that would be useful to them in terms of dealing
18 with sites and how they should operate, what good
19 practice on those sites might be?

20 A. Yes, yes there is. Some of the
21 broader classifications of land forms and vegetation
22 types have been recorded in tables. I have an overhead
23 that might help with that.

24 Q. Perhaps we can dim the lights.

25 MR. FREIDIN: I have a copy of that, Mr.

1 Chairman. Well, perhaps I will hand this out.

2 Q. Is there only one overhead that you
3 are going to be using?

4 MR. GREENWOOD: A. Yes, there is.

5 MR. FREIDIN: Okay. (handed)

6 THE CHAIRMAN: This will be Exhibit 461.

7 ---EXHIBIT NO. 461: Hard copy photograph of table
8 taken from booklet entitled:
9 Terrain Classification for
Canadian Forestry produced by
FERIC.

10 MR. GREENWOOD: This table was taken from
11 the little booklet that was produced for operators
12 practising -- field people, called: The Terrain
13 Classification for Canadian Forestry. It deals with
14 the boreal forest right across Canada and describes
15 some of the broad relationships between land form,
16 vegetation and soil moisture and soil texture.

17 It was produced primarily to allow
18 operators to get an indication of trafficability of a
19 site and, of course, if the site has low trafficability
20 it in fact could be a site that is susceptible to
21 rutting and compaction.

22 This was produced by the Forest
23 Engineering Research Institute of Canada, FERIC.

24 MR. FREIDIN: Mr. Chairman, could that
25 excerpt from that document be marked as the next

1 exhibit.

2 MS. SWENARCHUK: Excuse me. Could you
3 give me the title of the document again, please?

4 MR. GREENWOOD: Certainly. Terrain
5 Classification --

6 MR. FREIDIN: Oh, I didn't hear you, I
7 was busy.

8 THE CHAIRMAN: We already marked it.

9 MR. FREIDIN: What was it?

10 THE CHAIRMAN: 461.

11 MR. FREIDIN: 461. Thank you.

12 MR. GREENWOOD: Terrain Classification
13 for Canadian Forestry, a 1980 publication of the Forest
14 Engineering Research Institute of Canada, FERIC.

15 It just sets out some of those broad
16 relationships that I was referring too.

17 In the centre it talks about surface
18 deposits and in fact when describing land forms it can
19 be interpreted, and then it goes to two levels of
20 refinement, the overstorey vegetation and the forest
21 vegetation, again which I referred to, and the ground
22 vegetation which I referred to.

23 And, in a general way, the bottom line
24 shows the pressure required to operate on that site to
25 maintain productivity. By pressure, I mean the ground

1 pressure. If we go up in the table it relates it to
2 the two key characteristics that I referred to, the
3 moisture and soil texture.

4 MR. FREIDIN: Q. Now, Mr. Greenwood, as
5 you know I am terrible at interpreting things such as
6 this. Perhaps you could just take us through a couple
7 of those boxes and just tell us how we are to interpret
8 this. How would you actually read it.

9 MR. GREENWOOD: A. Okay. We start right
10 in the first block beside surface deposit. It is the
11 mention of types of deposits here, glacial deposits,
12 dune which is an aeolian, a windlain deposit or
13 glacio-fluvial deposits, waterlain, moving waterlain
14 deposits. And the table is telling us at the top that
15 that, in terms of trafficability is very good, it is
16 one, as opposed to the other extreme which is very poor
17 on the other side of the table.

18 It is telling us that it is -- in terms
19 of soil moisture, it is a freely drained, rapidly
20 drained site, so the water that is in the site is
21 moving through it, it is not being held. It is telling
22 us that that type of deposit would normally have coarse
23 sand or gravel.

24 If in fact it was a dune, it would be
25 fine sand, pure fine sand though without any silt

1 content. So it is giving us an indication of the soils
2 that are there.

3 Another flag as to what the
4 trafficability would be is given by the species that
5 could grow on that type of site. Normally on that type
6 of site the key species would be jack pine which is
7 particularly adapted to the limiting factors of a dry
8 site. You could, however, have black spruce
9 particularly if it is a mixture with jack pine or, to a
10 lesser extent, white birch and aspen.

11 The groundcover, you could examine it.
12 It could be lichen, if it was extremely coarse, it was
13 a coarse gravel deposit the only thing that may be able
14 to grow on it is lichen.

15 It could be any one of three other plants
16 that they would suggest are indicators on such a site,
17 bear berry, grass or feather moss. On that type of
18 site, the two that would be probably most common would
19 be feather moss and lichen.

20 Q. And the bottom line there is that is
21 basically the information which would -- could have
22 some indication as to the equipment that you could use
23 on that site; is that true?

24 It says approximate rated machine
25 footprint pressure required.

1 A. That's correct. It would be related
2 to the equipment that you could use or the equipment
3 that -- the ground pressure of the equipment you should
4 be using if you want to maintain trafficability.

5 Q. And what do you mean by
6 trafficability?

7 A. Ability to move around on the site.
8 An importance -- obviously when you have got equipment
9 on the site, of importance is productivity. If in fact
10 the equipment is unable to manoeuvre and move on the
11 site easily, you can reduce productivity as well as
12 create disturbance effects such as rutting.

13 In fact, the two go hand-in-hand rather
14 nicely in limiting the potential of this effect in that
15 when trafficability is low that is when you have a
16 condition where you could create compaction or rutting,
17 but it is also the point where productivity of that
18 equipment gets low and the equipment operators
19 obviously would prefer to be productive than
20 non-productive.

21 Q. Could I refer you to the witness
22 statement, Mr. Greenwood, and in particular page 491.

23 A. Yes, I have it.

24 Q. Now, page 491 is part of the section
25 which outlines conclusions - the conclusions start on

1 the page prior - of an article by Schurman and
2 Mackintosh. The actual article or the study starts on
3 page 468.

4 And my question for you -- the first
5 question is: Can you advise why this particular
6 document was included as part of the witness statement?

7 A. I utilized this article because it
8 gave a good description of the science involved in
9 compaction and rutting particularly as it related to
10 our most susceptible area.

11 Q. I believe it has a description of
12 this macro-porosity micro-porosity that you have
13 already spoken about?

14 A. Yes, it does.

15 Q. And on page 491 there is a comment,
16 if I can read to you or refer to you the first two
17 sentences on page 491:

18 "The study should be viewed as a
19 preliminary problem analysis on the
20 susceptibility of forest soils to
21 compaction in northern Ontario. To
22 determine the potential effects of
23 logging in this region, more extensive
24 research is needed on both mineral and
25 organic soils."

1 Could you advise: Have more detailed studies been
2 undertaken as suggested by the authors of this
3 particular document?

4 A. Not to my knowledge, no.

5 Q. And could you advise why not?

6 A. This particular document in the
7 authors' mind, even his conclusions was a preliminary
8 problem analysis, whether in fact there was a problem
9 there which warranted further study.

10 I think probably one of the key reasons
11 why further work wasn't requested by the Ministry was
12 that we had already determined that there were
13 potential negative effects of this type of action,
14 compaction and rutting, we didn't need further research
15 to tell us that. Sorry.

16 Q. Just before you go any further, this
17 particular study was a study conducted in the Clay
18 Belt?

19 A. That's correct.

20 Q. Okay. Sorry, if you could just
21 continue then.

22 A. There were also two developments that
23 took place at about the same time as this study was
24 completed. One was the release and wide-spread use of
25 the FEC for the Clay Belt, the first FEC produced in

1 the province, which allowed foresters to determine
2 susceptibility of the site to a rather refined level.

3 A second development was the advent of
4 the option of using wide tires to operate these areas
5 in summer. So with the ability to determine which
6 sites were susceptible and the ability to modify
7 equipment to prevent or minimize that effect, in fact,
8 we felt, or I assume - I don't know - I assume that it
9 was felt that there was no reason to do further study.

10 Q. Thank you. I would like to move on
11 and ask you a few questions about erosion. And again
12 this is a topic I think that was referred to by Mr.
13 Armson in Panel No. 9 and I think perhaps by some of
14 the witnesses on this panel.

15 Could you perhaps define what erosion is?

16 A. In a simple sense erosion is just the
17 movement of soil particles by a transporting agent and
18 the two transporting agents are wind and water,
19 particularly flowing water -- or only flowing water.

20 Q. I understand then that in your
21 evidence that you will be referring to wind erosion or
22 water erosion to make the distinction?

23 A. That's right.

24 Q. Can erosion occur due to harvest?

25 A. Yes, it can, although I would

1 suggest, as Mr. Armson has said, that it is extremely
2 limited. One has to be careful to separate erosion
3 from roads or landings, if they exist, from that which
4 occurs from the harvest operation across the site and
5 when you do this there is very little potential for
6 erosion from the harvest site.

7 Q. Erosion can occur as well from the
8 construction of roads; is that correct?

9 A. That's correct.

10 Q. And are your comments today and your
11 paper intended to address the potential for erosion
12 from roads?

13 A. No, it is not.

14 Q. Okay. You indicated that you agreed
15 with Mr. Armson's observation about whether or not
16 erosion was a problem. Are you able to -- are you
17 basing that on your own personal experience?

18 A. Yes, I am.

19 Q. And could you perhaps indicate to the
20 Board then what your personal experience has been which
21 causes you to agree with Mr. Armson's comment in Panel
22 No. 9?

23 A. If I could build on some comments you
24 made on your opening remarks where you said the
25 significance of an effect would be based on, I think

1 you listed four factors, the frequency, the intensity
2 the duration and the extent of any occurrence.

3 In terms of soil erosion, the severity of
4 occurrences that I have seen is extremely slight in
5 terms of the amount of soil that is actually moved and
6 I have never seen erosion to the point where it would
7 prevent ground vegetation from occurring or from
8 re-establishing on that site.

9 If you in fact don't reduce the ability
10 of vegetation to re-establish on a site, then the
11 duration of any effect is particularly short. As soon
12 as even a slight amount of ground vegetation is
13 re-established on the site, it will slow and in fact
14 can almost stop the process of erosion.

15 In terms of the extent of any occurrence,
16 the terrain within the area of the undertaking is quite
17 broken. I think you have probably seen that in your
18 travels in field visits. And because it is broken, if
19 in fact soil movement was to begin it would very
20 quickly be trapped in the depressions which exist
21 within that terrain and, therefore, the movement of
22 soil is quite limited even if the conditions were
23 created to allow it.

24 The potential frequency is the last point
25 I think you mentioned. And in terms of the area of the

1 undertaking we talked about the high permeability of
2 the soils. The high rate of infiltration throughout
3 most of the area of the undertaking, both due to the
4 nature of the texture of the soils itself plus the fact
5 that the organic matter just isn't disturbed to a
6 significant extent on areas that are harvested. And
7 because of those two factors the actual frequency of
8 any occurrence, again, is very slight.

9 Q. You indicate on page 248 of the
10 witness statement that soil erosion is a natural
11 process. Could you explain what you mean by that?

12 A. What I was really referring to here
13 was the fact that erosion is always taking place in our
14 environment, particularly along watercourses and
15 drainage ways.

16 So when we are talking about erosion, we
17 are not talking about an on/off situation, we are
18 talking about accelerated erosion. And I guess the
19 second point of calling it an actual disturbance --
20 sorry, a natural occurrence is the fact that
21 disturbance takes place regularly within our
22 environment and disturbance, whether it is man-caused
23 or natural, can accelerate this erosion.

24 Q. Have you ever measured the amount of
25 erosion or gathered data on its occurrence following

1 harvest?

2 A. No, I have not. In fact, I am not
3 aware of any studies in Ontario or for that matter
4 eastern Canada that has in fact measured erosion from a
5 site as a result of harvest and that would be as
6 opposed to roads.

7 The other thing in terms of measuring,
8 erosion -- when I am referring to erosion, I am
9 referring to its ability to affect productivity on the
10 forest estate and any erosion which could affect
11 productivity in a significant way would be quite
12 visible and it just isn't an occurrence that is
13 visible.

14 Q. And your experience is not one that
15 you have seen; is that what you mean?

16 A. That is correct. You mentioned
17 experience earlier. I maybe make one other point. It
18 is not just experience in seeing erosion. The factors
19 which control erosion I think are fairly well
20 understood, it has been studied for many years,
21 probably centuries, and an understanding of those
22 principles plus an understanding of the conditions
23 which occur after harvest is what would allow one to
24 come to the conclusion that the potential for erosion
25 is very slight.

1 So it is not just observation of visible
2 erosion or lack thereof, it is observation of the
3 conditions which exist following harvest when compared
4 to the conditions which would need to exist for erosion
5 to take place.

6 Q. Okay. Well, that gets me really I
7 think into the next area of this topic of erosion that
8 I would like to get into and that is, that even though
9 the occurrence of erosion is not significant because of
10 harvest, would the factors which could lead to erosion
11 be the same regardless of the timber management
12 activity that you were considering?

13 A. Yes. I have been limiting my remarks
14 to harvest but in fact those principles -- the factors
15 would create -- would apply to all practices in timber
16 management.

17 Q. All right. Well, it's those
18 principles and factors that I would like to get into.

19 Do I understand that it will be important
20 to understand these factors or these principles not
21 only for understanding your evidence in this panel, but
22 it will in fact enable a better understanding of
23 evidence to be given in later panels?

24 A. That's correct.

25 Q. All right. So let's just deal with

1 these factors or principles for a moment. What sort of
2 conditions must exist before a site will erode?

3 A. Well, there is two key conditions
4 that I think you have to keep in mind. The first is
5 that the soil itself, the mineral soil has to be
6 exposed over relatively large and continuous areas.

7 By exposed I am referring to removal of
8 the forest floor. With the forest floor in place at
9 litter layer, the duff layer promotes infiltration of
10 water into the soil which leads me to the second key
11 factor, you have to have an agent of movement something
12 that can move the soil, and we referred earlier to wind
13 and water.

14 In the case of the removal of the organic
15 layer, it is that removal which exposes the soil to
16 those agents of wind and water and if that soil isn't
17 exposed then it can't erode.

18 Q. Is the removal of the forest floor
19 and the resulting exposure of the soil to wind and
20 water common as a result of harvest?

21 A. No. As I have already said, I think
22 that occurrences are very slight, limited in extent.

23 Another factor that you have got to keep
24 in mind when looking at erosion in the area of the
25 undertaking is the fact that we have winter for about

1 half a year and under winter conditions the soil is
2 frozen and it can't -- it would be more difficult to
3 erode, particularly if it was protected in a blanket of
4 snow, but if operations take place during this time, it
5 would be very unlikely that you would affect that
6 forest floor.

7 Q. Now, where exposure of the mineral
8 soil does occur, are all sites equally susceptible to
9 erosion?

10 A. No, they are not.

11 Q. All right. And could you explain why
12 all sites are not equally susceptible to erosion when
13 you have that exposure of the mineral soil?

14 A. Like compaction and rutting, probably
15 the key characteristics relate to the soil itself.
16 Even if the soil was exposed, it would depend on the
17 texture that's there -- or the texture that's there
18 would determine whether the potential for erosion was
19 significant or not.

20 If you expose a coarse sand, the
21 coarseness of the sand would prevent wind from moving
22 it to any great degree and the coarseness of the sand
23 would prevent surface runoff from the area. If water
24 hits that exposed sand, it would infiltrate into the
25 sand and, therefore, not move over the surface and not

1 create the action necessary to erode it with water. So
2 the soil texture is a key factor.

3 The second key factor would be the
4 abundance, or particularly the lack of stablization
5 factors on the site and there are -- these would equate
6 I guess to some of those protection factors that I
7 mentioned in compaction and rutting. Roots, again, can
8 hold soil to prevent its movement. The depressions in
9 the terrain that I spoke to which could limit any
10 occurrence would also be another stablization factor.

11 Q. Okay. You gave an example of a soil
12 texture, coarse sand, which would militate against
13 erosion occurring. Could you give an example of a soil
14 texture which would perhaps be more susceptible to
15 erosion if it was exposed?

16 A. The texture that would have the
17 highest potential -- in fact, really within the area of
18 the undertaking the only significant potential for wind
19 erosion is a pure fine sand. I think this was referred
20 to by Mr. Hynard in his evidence, he referred to a
21 silt-free fine stand.

22 By pure fine sand we mean that it does
23 not contain significant amounts of sand particles of
24 different sizes, they are all fine, they aren't coarse,
25 they aren't very fine and there is no component of

1 other materials like silt in that sand. For wind
2 erosion to occur you would also have to have not only
3 the fine sand but the lack of those stabilizing
4 factors.

5 Q. All right. And in terms of water
6 erosion, are you able to indicate a soil texture which
7 would be perhaps more susceptible to that occurring if
8 you had all the conditions occurring, more susceptible
9 than this coarse sand that you refer to?

10 A. Yes. The finer-textured soils tend
11 to be more erodible by water.

12 When we are referring to water erosion
13 there is maybe something else, we are talking about
14 susceptibility by texture. A point that I haven't
15 mentioned is that for water erosion you not only have
16 to have the susceptibility of the site in terms of
17 texture to create erosion, but the site has to be
18 susceptible to water movement as well, surface runoff.

19 So obviously the site must have some
20 slope. If it is flat, the susceptibility for water
21 runoff is greatly reduced.

22 The forest floor, again, is an important
23 point. If the forest floor is in tact or if its
24 integrity is in tact, then you would not get surface
25 runoff, the water would infiltrate the forest flow --

1 the forest floor and run below surface.

2 Another factor that may play a part in
3 surface runoff is reduced soil porosity. So if
4 compaction had taken place on a site you could in fact
5 create conditions for soil -- surface water runoff. So
6 in terms of water erosion, you not only have to have a
7 susceptible soil, you have to have the soil in a
8 condition where water runoff could take place.

9 Q. And I understand that in Panel 11
10 there is going to be evidence about site preparation
11 which in fact involves, in some cases, the intentional
12 exposure of the soil?

13 A. That's correct.

14 Q. And I don't want to sort of get into
15 Panel 11 at all, I understand that you will be a
16 witness there as well, but does that activity where you
17 intentionally expose the soil, does that increase the
18 potential for erosion?

19 A. Yes, it does. And when we in fact
20 carry out site preparation operations, or when we are
21 doing those descriptions, the prescription of equipment
22 and its use would take into account the factors which
23 could accelerate erosion.

24 Q. All right. And we will be dealing
25 with that in Panel 11?

1 A. That's correct.

2 Q. Where did you learn about these
3 principles or factors which are relevant when assessing
4 susceptibility to erosion, Mr. Greenwood?

5 A. I mentioned a minute ago that the
6 principles have been well known for a long time and I
7 am sure that from before I got to university - though,
8 I don't remember - I understood some of the basic
9 principles of erosion. However, in university, in
10 Faculty of Forestry, they related the practices of
11 timber management particularly to the principles of
12 erosion. So it was part of my academic training.

13 Q. Does the understanding -- in your
14 personal experience, does the understanding of these
15 principles vary as between foresters?

16 A. I think the understanding probably
17 would vary, yes, in that, I suppose depending on your
18 academic training, there may have been focuses which
19 were different between foresters.

20 However, it has certainly been in my
21 experience that all foresters that I have worked with
22 have an understanding of soil erosion and the effects
23 of timber management practices to a level that allows
24 them to make reasonable silvicultural and harvest
25 decisions.

1 Q. You described --

2 MR. FREIDIN: If I can just have one
3 moment, Mr. Chairman.

4 Q. When we dealt with the subject matter
5 of compaction and rutting, you indicated some of the
6 sources of information or cues that a forester might
7 have as to whether your site was susceptible to that or
8 not, you referred to land forms and you referred to the
9 FEC and such things.

10 Where does a forester get information
11 which would allow the forester to apply the principles
12 in terms of erosion that you have described?

13 A. When I discussed compaction and
14 rutting I grouped the information into two areas,
15 direct and information -- direct and indirect sources.
16 The same would be true for erosion. The direct sources
17 certainly exist, you can go out to the field and
18 observe directly some of these factors.

19 It may be through the direct observations
20 of others that the information becomes available; it
21 may be through those direct observations, for instance,
22 which are recorded in a soil survey, there are -- or a
23 land form map, we talked about land forms affecting
24 texture.

25 There are also indirect methods which

1 apply equally to erosion, aerial photographs, flyovers
2 of the area. There is a number of different methods of
3 direct and indirect sources of information, methods or
4 sources of information.

5 Q. All right. Are these sources of
6 information available to field foresters?

7 A. The majority of the sources are
8 readily available throughout the area of the
9 undertaking, yes.

10 Q. And when you say the majority of the
11 sources are readily available, does that mean there are
12 some sources which aren't readily available? I am not
13 too sure exactly what you mean when you say that.

14 A. Yes, I think that's what I meant.
15 For instance, I guess an example, soil -- detailed soil
16 surveys that would give you the detailed level of
17 information necessary to determine susceptibility to
18 erosion do not exist throughout all areas of the
19 undertaking. So that would be one that wouldn't be
20 available everywhere.

21 Q. All right. So when you say the
22 majority of these sources are not readily available, it
23 is because in some areas they don't even exist?

24 A. That's correct.

25 Q. Okay. In your experience, do other

1 foresters use these tools that you have referred to in
2 the same way that you do?

3 A. Well, I didn't do a survey of
4 foresters before I wrote this evidence, but certainly
5 the ones that I worked with did and that has been the
6 experience of other foresters. It would be to a lesser
7 or greater degree I think depending on which method you
8 were talking about.

9 One just crossed my mind, that when we
10 are talking about aerial photographs and interpreting
11 them for things such as land forms and soil textures,
12 some people can't see stereo using these photographs;
13 that is, they can't see the three dimension that stereo
14 photographs can let you see.

15 In a circumstance like that, it would be
16 very difficult for a forester to use that particular
17 tool to any great extent.

18 Q. Is it necessary to use all of these
19 tools to make decisions on every site?

20 A. No, definitely no.

21 Q. Could you explain that?

22 A. Well, when you are looking at things
23 such as susceptibility, and erosion is a good example,
24 you are usually looking for -- or utilizing flags or
25 cues that there is a potential there.

1 If I could use the aerial
2 photointerpretation as an example. If you are looking
3 at an area and determining land forms or even looking
4 at the vegetation, a flag that might hit you is a sand
5 dune. These are in fact visible on aerial photographs.
6 These are sand dunes that were probably created during
7 glacial times and they are quite large and as soon as
8 you saw a flag or a cue such as that, you would know
9 that the soil texture there has a potential for wind
10 erosion.

11 Q. Now, a number of witnesses, and I
12 think probably more so with Mr. Armson, have described
13 the importance of integrating harvest and renewal
14 decisions. If we could stick with this topic of
15 erosion for a moment, can you indicate how this
16 integration might come into play?

17 A. Probably the best way to do that
18 would be to build on the example that I have just
19 given.

20 If in fact a forester picked up a flag or
21 a cue such as these sand dunes, there would be concern
22 for renewal activities, particularly site preparation
23 that would follow the harvest. The areas that would
24 have sand dunes would normally be growing almost pure
25 jack pine stands because of the dry nature of the site,

1 and jack pine does require a degree of mineral soil
2 exposure to regenerate, particularly artificially.

3 So the forester would be looking at that
4 site knowing that the renewal activity would have to
5 provide some degree of mineral soil exposure or at
6 least a very thin duff layer so that the roots would be
7 in the mineral soil. And, in prescribing harvest,
8 could possibly take this into account by prescribing
9 clearcut, of course, for jack pine because it needs
10 full light by using the tree-length method so that
11 sufficient slash is left on the site to allow
12 prescribed burn, for example.

13 If that forester was concerned about
14 opening the mineral soil on that site, the concern
15 would be for mechanical treatment, then the alternative
16 would be to use something like prescribed burn but such
17 a burn can only be carried out if in fact there was
18 sufficient slash on the site to carry the burn.

19 So I think that's maybe an example of how
20 picking up a cue or a flag could in fact lay into place
21 a number of decisions or prescriptions that would show
22 the inter-relationship between harvest and renewal.

23 Q. All right. And the concern about the
24 mechanical site prep exposing -- I guess tilling the
25 site in effect, would be a concern because of the

1 potential for wind erosion in that situation?

2 A. Yes. We talked about sand dunes
3 here. So the potential is not for water erosion, the
4 potential on a dry site like that would be for wind
5 erosion.

6 In terms of mechanical site preparation,
7 again, the concern would be for the degree of soil
8 exposure which took place. If in fact the organic
9 matter stays in place or its continuity stays in place,
10 the degree of susceptibility for wind erosion would
11 still be quite low.

12 Q. Okay.

13 A. But his preferred method may be a
14 prescribed burn.

15 Q. Now, if erosion did occur in a
16 significant way, would that erosion be of concern if
17 you are talking about the effect on the forest estate,
18 the productivity?

19 A. If it occurred in a significant way,
20 yes, it could be a concern.

21 Q. And what would be the concern? It
22 may be a very obvious question, but let me ask it any
23 way: Why would the erosion be a concern in terms of
24 the potential to affect productivity?

25 A. That's the answer, for the potential

1 to affect productivity.

2 Q. I guess if you wash the soil away...

3 A. If the -- most of the nutrients in
4 the soil are in the upper layers of the soil, Mr.
5 Armson talked about the weathering that takes place in
6 the soil and that in fact within that weathered area is
7 where most of the nutrients are. If erosion was deep
8 enough to remove a significant portion of that soil,
9 you are in fact removing the nutrients from the site
10 and that can obviously affect not only productivity but
11 the ability to renew the site.

12 Q. In your personal experience, are you
13 aware of erosion which has occurred which has adversely
14 affected the ability to renew a site?

15 A. Not at all.

16 Q. And for there to be -- and Mr.
17 Greenwood, I understand that in Panel No. 11 the
18 Ontario Federation of Anglers & Hunters asked an
19 interrogatory, Interrogatory No. 18, which asks some
20 very general questions about techniques which are
21 available to predict erosional losses and documentation
22 of what is done on a site; is that correct?

23 A. That's correct.

24 MR. FREIDIN: And, Mr. Chairman, I would
25 like to file that particular interrogatory as the next

1 exhibit.

2 THE CHAIRMAN: 462.

3 ---EXHIBIT NO. 462: Interrogatory No. 18 of OFAH to
4 Panel 11.

5 MR. GREENWOOD: I might just add, Mr.
6 Freidin, you asked me about the concern for erosion. I
7 restricted my remarks to the forest estate which my
8 evidence was on. I think we heard yesterday about the
9 obvious concern for significant erosion in terms of its
10 effect on sedimentation or turbidity of watercourses,
11 and this is something that you would have to keep in
12 mind as well.

13 MR. FREIDIN: Q. Now, your evidence has
14 been directed -- focused primarily at the forest
15 estate?

16 MR. GREENWOOD: A. Yes. My concern in
17 terms of this evidence would be for productivity of the
18 site.

19 Q. Okay, thank you.

20 MR. FREIDIN: Mr. Chairman, I am going to
21 move on to the area of micro-climate and it is going to
22 take well past the break, I believe. This might be a
23 convenient time for a break.

24 THE CHAIRMAN: Very well. We will break
25 for 20 minutes. Thank you.

1 ---Recess taken at 10:25 a.m.

2 ---Upon resuming at 10:50 a.m.

3 THE CHAIRMAN: Thank you. Be seated.

4 MR. FREIDIN: Mr. Chairman, I would just
5 like to advise that it is my information that there is
6 a meeting scheduled for noon to deal with this clearcut
7 methodology, and I believe that some of the counsel
8 present were hoping to attend that meeting. So I would
9 just like to indicate that I will be asking that we
10 break at noon as opposed to the usual 12:30.

11 THE CHAIRMAN: We are not invited, I take
12 it?

13 MR. FREIDIN: I have nothing do with it,
14 Mr. Chairman.

15 THE CHAIRMAN: Okay. We will break at
16 noon. And what are you suggesting, that we break until
17 what, two o'clock?

18 MS. SWENARCHUK: Two o'clock.

19 THE CHAIRMAN: Okay.

20 MR. FREIDIN: I think so. I have just
21 been looking at what is happening here, I think that we
22 will probably finish Mr. Greenwood 3:30.

23 THE CHAIRMAN: 3:30?

24 MR. FREIDIN: Three or 3:30, somewhere
25 around there. We will probably get a start on Mr.

1 Clark and a good chance of completing Mr. Clark
2 tomorrow by noon, by the lunch break.

3 THE CHAIRMAN: Okay.

4 MR. FREIDIN: Okay.

5 Q. So, if I can move on to the subject
6 of micro-climate which is one of the areas that you
7 indicated that you wanted to speak about.

8 MR. FREIDIN: And, Mr. Chairman, Mr.
9 Armson did touch on this by way of example, but I feel
10 that it is important to sort of discuss this particular
11 topic as one package, so I apologize if there may be
12 some repetition or reference to Mr. Armson, but it will
13 be brief.

14 Q. Mr. Greenwood, what is micro-climate?

15 MR. GREENWOOD: A. Well, for the
16 purposes of the evidence, I have just defined it as the
17 climate from the forest floor surface to the canopy
18 cover.

19 Q. And could you advise: What are the
20 elements of that micro-climate?

21 A. There is a number of main elements.
22 Obviously the first one that we would be concerned with
23 within that area is temperature and for purposes of
24 micro-climate the temperature is broken into two
25 different temperatures, the surface temperature and the

1 air temperature.

2 And it is separated to distinguish the
3 fact that the temperature can be quite different
4 between the surface and even as much as a quarter metre
5 above it. A good example of that I think would be
6 walking on a sand beach and burning your feet, but you
7 are not burning your knees. It can be quite dramatic,
8 the solar radiation on the forest floor in terms of
9 heating.

10 The second one would be the amount of
11 light within that area, the third one would be wind or
12 wind movement within the area defined, the humidity
13 within that area, and the last one, in terms of the
14 main elements, would be the amount of precipitation
15 that hits the forest floor.

16 Q. Okay. And why are these particular
17 elements important?

18 A. Well, the elements in combination
19 which create micro-climate are important particularly
20 in terms of the effect that they can have on a species'
21 ability to regenerate and, again, within that early
22 growth period when they would be fairly close to the
23 ground, particularly as that growth rate could affect
24 their ability to survive and compete after they have
25 regenerated.

1 Q. Okay. Does harvest have any effect
2 on that micro-climate?

3 A. Well, if it is defined as area from
4 the surface to the canopy, obviously if you remove that
5 canopy it can have an effect. It can change all of the
6 factors depending on the degree to which you open the
7 canopy.

8 Q. All right. Could you perhaps
9 describe the micro-climate in a situation where -- or
10 compare, I guess, the micro-climate in a situation
11 where on the one hand you have a closed canopy, and
12 where on the other hand you have opened the canopy?

13 A. Within a closed canopy, if you look
14 at the first factor that we talked about, temperature
15 both of the surface and the air, that canopy will
16 moderate the changes in temperature that will take
17 place. The daytime temperatures will be cooler in both
18 cases due to the shading effect of the canopy and the
19 nighttime temperatures would be warmer as a result of
20 the canopy holding the warmer air in.

21 Also, within a closed canopy there would
22 be reduced light, the same shading that reduces the
23 temperature is reducing light.

24 In terms of wind, the forest floor,
25 particularly in the area under the canopy, is protected

1 from large amounts of wind movement. The relative
2 humidity would be higher under a closed canopy,
3 moisture is retained, less is evaporated and less
4 precipitation would in fact hit the forest floor as a
5 result of the interception that takes place at the
6 forest canopy and the evaporation from that canopy.

7 In terms of opening the canopy, it would
8 again depend on the degree to which you open the
9 canopy, but as you open the canopy and solar radiation
10 can enter further down or what would have been below
11 the canopy, you would raise the surface temperature,
12 you would raise the air temperature, but at nighttime,
13 because you don't have the protection of that canopy,
14 the opposite effect would take place and, in fact, your
15 nighttime temperatures would be much cooler.

16 Light is obviously increased with opening
17 the stand, the ability for air movement to take place
18 in the form of wind would be greater, humidity as a
19 result of that wind movement would be less, and the
20 precipitation hitting the floor would obviously
21 increase if there isn't vegetation to intercept it.

22 Q. And what is the result of a change in
23 the micro-climate in general terms?

24 A. Well, in general terms the overall
25 effect would be to change the characteristics for

1 growth on that site, the characteristics of site which
2 would affect growth.

3 Q. And in terms of opening the stand,
4 would the change in that micro-climate vary with the
5 degree of opening of the canopy?

6 A. Yes, it would.

7 Q. I am just wondering if you could take
8 those particular elements of the micro-climate, Mr.
9 Greenwood, and describe how those factors not only
10 might change due to harvest - I think you have perhaps
11 explained that already - but indicate how the
12 particular changes could affect growth and perhaps by
13 way of giving us examples of situations in the field?

14 A. Okay. In terms of surface
15 temperature - and I have to keep emphasizing that this
16 will relate to the degree of stand opening - but in
17 terms of surface temperature we heard in Panel 9 about
18 how the increased temperature that takes place
19 following harvest can lead to increased rates of
20 decomposition of the organic matter and, therefore,
21 release of nutrients and this would have an effect on
22 the ability or the growth rate that would take place on
23 the site. That would be considered a positive effect
24 of change in micro-climate.

25 Another positive effect -- or an example

1 of a positive effect of increased surface temperatures
2 would be the ability of those temperatures to open
3 serotinous cones. Mr. Oldford described one of the
4 methods of natural regeneration of jack pine would be
5 to leave slash throughout the site. That can only be
6 effective if both the surface and the air temperature
7 is high enough that those cones will open with the
8 heat. So, again, another positive effect.

9 In terms of a potential negative effect
10 of increased surface temperature, this temperature
11 could in fact dry out the litter layer and what may
12 have been an appropriate seedbed while it was shaded
13 would no longer be an appropriate seedbed for renewal
14 of some species because of this dry litter layer.

15 In air temperature, I think I mentioned
16 or I would have already said, that we are talking about
17 extremes. If in fact those colder temperatures that we
18 referred to create an ability for frost to settle on a
19 site, you could have a negative effect for some
20 species. Again, I think Mr. Armson referred to white
21 spruce and its inability to -- or its susceptibility to
22 late spring frosts.

23 At the same time, the warmer temperatures
24 during the day can be important for seedling growth
25 after renewal has taken place and this surface

1 temperature -- sorry, the air temperature, again,
2 effect on jack pine cones.

3 An obvious example of an effect of
4 increasing light would be the ability of intolerant
5 species to regenerate. Jack pine/poplar would not
6 regenerate in the shade of a canopy and by opening the
7 stand you are creating a positive benefit in lieu of
8 those species.

9 When I mentioned wind, I talked about its
10 ability to decrease humidity. That could be a negative
11 effect if it adds to drying the site out for some
12 species. It could in fact, if it is severe enough,
13 dessicate or dry out young regenerating forest
14 vegetation and, therefore, limit its ability to
15 establish. And in terms of humidity itself, it would
16 decrease in relation to the amount of stand opening and
17 that also could affect the ability of the site to dry
18 out.

19 The last measure of micro-climate, the
20 amount of precipitation hitting the floor. Again, we
21 heard in Panel 9 how it is not only the increased
22 temperature but the increased moisture that is in the
23 forest floor that will increase the rate of
24 decomposition and, therefore, releases nutrients. So
25 the increase in precipitation or soil moisture can have

1 a positive effect and obviously increased precipitation
2 hitting the floor and, therefore, being held in soil
3 moisture can affect the ability of the trees to grow or
4 their growth rate.

5 Q. So these changes in micro-climate
6 then have potential to be positive or negative
7 depending on the particular site that you are dealing
8 with?

9 A. That's correct, site and species.

10 MR. FREIDIN: If I can just have a
11 moment, Mr. Chairman.

12 Q. Could you provide perhaps just a few
13 more examples about how knowledge about micro-climate
14 could affect decisions regarding harvest?

15 A. I think in most of the positive
16 effects and negative effects that I referred to it was
17 fairly obvious that we are talking more about renewal
18 of the site or at least we are centering on the topic
19 of renewal of the site, so I would use some examples of
20 that.

21 I have referred to the jack pine slash
22 being opened by the increased temperatures. Knowing
23 that jack pine is an intolerant species and requires
24 full light, and knowing that the cones are serotinous,
25 this would lead you to in fact prescribe a clearcut for

1 the area which would provide the light that is
2 appropriate for renewal and you might also -- you would
3 have to prescribe the tree-length logging method to
4 distribute the slash across the site to take advantage
5 of the increased temperatures and opening the cones.

6 Q. So in that particular example then
7 the logging method and the harvest system would be
8 chosen based on an understanding of how micro-climate
9 might be changed?

10 A. That's correct.

11 Q. Okay. Can you give me another
12 example?

13 A. Another example would be knowing that
14 upland black spruce requires, if you were using natural
15 regeneration, a seedbed of moist spagnum moss and that
16 if you opened the stand completely you could increase
17 the temperature and wind movement to the point that
18 that seedbed could dry out and no longer be
19 appropriate. However, you would also have to consider
20 the fact that black spruce requires, for appropriate
21 renewal rates, increased light even though they are
22 semi-intolerant -- semi-tolerant they grow better in
23 full light.

24 So knowing these various factors you
25 would prescribe probably strip cuts which would modify

1 the micro-climate on the site to the point that the
2 seedbed would not dry out by providing increased
3 shading as opposed to opening the site completely
4 reducing the wind movement which could cause
5 dessication of that seedbed and you would determine the
6 width of that strip, I think depending on the degree
7 with which you wanted to affect that micro-climate.

8 Q. Mr. Hynard -- and those examples that
9 you chose were sort of boreal forest region examples.

10 A. That is correct.

11 Q. And, Mr. Hynard, could you based on
12 your experience in the Great Lakes/St. Lawrence region,
13 perhaps provide an example or two about how knowledge
14 regarding micro-climate can affect decisions regarding
15 harvest?

16 MR. HYNARD: A. Yes. I think of the
17 example of the use of the shelterwood harvest system to
18 reduce the drying effects of sun and wind in the
19 regeneration of species that are vulnerable to seedling
20 dessication. White pine and yellow birch are good
21 examples. Those seedlings like to have a little bit of
22 protection from those drying effects during their first
23 year.

24 Q. And what sort of harvest prescription
25 would you -- might you adopt in order to address that

1 concern?

2 A. Well, let's take the example of the
3 white pine. If you were relying upon a natural
4 regeneration method you would -- you may select the use
5 every uniform shelterwood, in which case those drying
6 effects of sun and wind are reduced on the natural
7 fresh germinates that are regenerating.

8 If, on the other hand, you were
9 regenerating by artificial means for other reasons,
10 same species, you might not select that harvest system
11 because those effects are not important in the use of
12 nursery -- bareroot nursiey stock.

13 Q. Mr. Greenwood, could you turn to page
14 254 of the witness statement, please.

15 MR. GREENWOOD: A. Yes, I have it.

16 Q. I refer you to the first full
17 paragraph.

18 MR. FREIDIN: Page 254.

19 Q. The first full paragraph states:
20 "Should micro-climate effects be
21 determined to be detrimental
22 to forest establishment or growth, they
23 can be PREVENTED, MINIMIZED or MITIGATED
24 through control of harvest layout,
25 harvest method, degree of

1 utilization, protection (e.g. winter cut)
2 or establishment of ground vegetation and
3 choice of regeneration species."

4 Firstly, are there any corrections that you would like
5 to make to that paragraph?

6 MR. GREENWOOD: A. Yes. Harvest method
7 should read harvest system.

8 Q. That is in the third line?

9 A. That's correct.

10 Q. There's a reference to establishment
11 of ground vegetation playing a role on the effect that
12 a change of micro-climate might cause. Could you
13 perhaps give me an example of how the establishment of
14 ground vegetation could play such a role?

15 A. Yes. I would go back to the white
16 spruce susceptibility to late frosts. One of the ways
17 that you could affect micro-climate in a way that would
18 reduce or minimize this effect, would be to maintain
19 the vegetation on the site which in fact could
20 moderate - similar to what the canopy had done before
21 it was removed - the extremes in temperature that the
22 white spruce would be exposed to.

23 Q. And could you provide an example of
24 how the choice of species to be regenerated could
25 address potential effects of micro-climate?

1 A. Yes. Again in the white spruce
2 example, if the area was particular susceptible to
3 forst and you weren't able to affect that, you could
4 move to black spruce as a species which is not as
5 susceptible to those late spring frosts because they
6 flush at a later date.

7 Q. I think the question probably would
8 have been more correctly the potential effects of a
9 change in micro-climate.

10 A. That's right.

11 Q. Moving on for a very brief discussion
12 of insect and disease sanitation which is the subject
13 of a section on page 254 and 255, what are you
14 referring to when you are talking about insect and
15 disease sanitation?

16 A. Very simply it is the ability of
17 harvest to afford some degree of insect disease and
18 control.

19 Q. It is the control of insects and
20 disease?

21 A. Correct.

22 Q. Could you provide an example of how,
23 or when harvest might take place in order to control
24 insects and disease?

25 A. One of the ones which has been more

1 prevalent in the area of the undertaking over the last
2 little while is the acceleration of harvest of white
3 spruce and balsam fir to limit the spread of the spruce
4 budworm which was in a severe outbreak within the area
5 of the undertaking -- well, has been now for over ten
6 years.

7 Q. And why would you accelerate the
8 harvest of those species?

9 A. Well, two reasons: In terms of
10 control of the insect you are removing a source of food
11 and a source -- and a habitat for breeding. I guess
12 the second reason would be that you are attempting to
13 utilize those species before the insect harvests it.

14 Q. Okay. And is there any other example
15 that you could give of harvest being used as a means of
16 controlling or limiting insect and disease?

17 A. Another example that I am familiar
18 with personally is the clearing or removal through
19 clearcutting of certain trees, diseased trees
20 particularly in the vicinity of high value stands such
21 as seed orchards or in the vicinity of areas such as
22 nurseries, where the disease that is in those trees is
23 one which could in fact move into the younger trees or
24 the higher value trees and spread within them.

25 Q. Okay. Mr. Hynard, is there anything

1 that you could add perhaps by way of example from the
2 Great Lakes/St. Lawrence?

3 MR. HYNARD: A. I can't think of an
4 example in which you would actually -- where your
5 harvest would actually sanitize a stand. I think you
6 would almost have to boil your trees for 20 minutes to
7 get that effect.

8 But I think of similar cases where we
9 have made intentional harvest allocation of stands,
10 particularly red oak, that were showing signs of tree
11 decline. I think the main purpose there is not to
12 confine tree decline, but rather to capture that wood
13 before it was lost.

14 But in the selection harvest system, the
15 integration of the harvest with tending to reduce the
16 number of defective trees in the stand at the same time
17 the harvest is being carried out is an example of some
18 degree of sanitation.

19 Q. Okay, thank you. The last area that
20 you indicated that you were going to address, Mr.
21 Greenwood, is the area of forest diversity. And I
22 believe that discussion begins on page 255 of the
23 witness statement and carries through to the end pretty
24 well. Could you begin by telling us what you mean by
25 forest diversity?

1 MR. GREENWOOD: A. When I use the term I
2 simply meant it to mean the diversity or the
3 variability that is in the forest.

4 Q. And when you talk about diversity or
5 variability within the forest, are you going to be
6 addressing certain types of diversity?

7 A. Yes. I broke the subject area into
8 three separate topics: Species diversity, age
9 diversity, and genetic diversity as three areas that in
10 fact harvest could have a potential impact on.

11 Q. Now, your paper makes a distinction
12 between diversity in relation to those three things;
13 species, age, and genetics within a stand and as
14 between stands?

15 A. Correct.

16 Q. Could you perhaps explain to the
17 Board what it is you are really talking about when you
18 make that distinction?

19 A. Well, I have decided, Mr. Freidin, to
20 use a flip chart for this because of some of the fun we
21 had trying to explain it to you. So I am going to
22 attempt to show it in a clear way.

23 Q. You mean I am going to understand it
24 when you finish.

25 THE CHAIRMAN: That is making some

1 assumptions that may not altogether be true, Mr.
2 Greenwood.

3 MR. GREENWOOD: Yes. I also do not draw
4 very well, so I will have to do this somewhat
5 schematically.

6 What I thought I would do to try and put
7 our arms around this one would be to first of all
8 conceptionally walk you into a stand and just point out
9 some of the things that you might see in terms of
10 diversity as you went. And if in fact we were parked
11 on the side of a road looking at a stand, one of the
12 things that you would see is that in the canopy there
13 is different shapes and, in fact, these shapes would
14 reflect different species and, therefore, within that
15 stand you could see diversity in species.

16 Another thing that when you walk into the
17 stand you might see is that when you look at one
18 particular species there is variability within that
19 species in its form and you might see that some of the
20 stems are in fact curved or rippled, some of the stems
21 are fairly large in diameter, others are small in
22 diameter.

23 You might see that some particular trees
24 within that species all have very sharp branch angles,
25 an upward angle, others are perpendicular to the stem.

1 And what you are in fact seeing are differences that in
2 fact can reflect genetic diversity within that stand.
3 The different growth rates, different shapes of stems,
4 branch angles are things which are fairly heavily
5 controlled by the genetic variability within that
6 stand.

7 MR. FREIDIN: Q. I understand that later
8 on we will come back to that comment where you say the
9 differences can reflect genetics, I understand later
10 you will be explaining that in fact what you are seeing
11 might not necessarily be the result of genetics?

12 A. That's correct.

13 Q. Okay.

14 A. Another thing that you see in this
15 stand, you are going to see is that there are trees
16 also in the understory, they may be the same species.
17 In this particular case I am in the boreal forest and
18 they are probably not the same species because they
19 would be tolerant and the canopy species would be
20 intolerant.

21 These species generally are advanced
22 growth which has come into the stand and, therefore,
23 you are seeing a manifestation of age diversity within
24 this stand. So in fact within the same stand we are
25 seeing diversity of species, diversity of ages, and

1 indications that there is genetic diversity within the
2 species that are there.

3 Now, if we were to get into a truck and
4 start moving down the road and checking stands as we
5 go, it is quite possible that we would see some of the
6 same species in slightly different arrangements. We
7 might see the same species as was in this mixed stand
8 but all in a pure stand and, therefore, a stand where
9 there isn't a species diversity now within the same
10 stand.

11 You might -- this stand, in this case, is
12 much smaller than the other stand, the site type isn't
13 that different and, therefore, you would infer that
14 this is a much younger stand. So now we have created
15 age diversity between the stands.

16 You do notice, however, that the same
17 characteristics of individual stems were also in this
18 stand in that the variability in stem form; that is,
19 some crooked, some rippled, some straight, is also
20 within the species in the smaller stands; some are
21 crooked, some are rippled, some are straight. This
22 would be a rather distinct boundary in terms of
23 creating diversity between the stand but in itself it
24 is another stand and can have varying levels of
25 diversity within it.

1 As you go further you may find a canopy
2 which is the same size as those which were in the
3 original stand we went to, still has diversity, but the
4 species mixture changes slightly and where there was a
5 heavy component of blue trees here, now the heavier
6 component is to the red trees.

7 So in this case there is still species
8 diversity within the stand just that the species have
9 changed. And in this particular stand you also notice
10 the same factors that could be controlled by genetics
11 are there. In this particular stand, we also may have
12 an understorey so, therefore, within the stand we have
13 age diversity again.

14 So you are noting as you are going down
15 the road that there are differences as you go past
16 three stands not only in the diversity in those three
17 factors that exist within each stand, but the diversity
18 that exists between the stands.

19 The last part of the trip, if we were to
20 lift off the ground now in a helicopter and look at
21 this from above, you would see in fact that the spacial
22 distribution of this -- of these species is repeated
23 throughout the whole area and, in fact, a mosaic is
24 formed of the differences between stands recognizing
25 that still there are difference within stands.

1 And that might be reflected particularly
2 on an FRI map by the fact that this was a poplar stand,
3 with 80 per cent poplar; jack pine 20 per cent; species
4 diversity, but as we cross along line here where we
5 have poplar 100 per cent there is also diversity and a
6 very sharp edge between those, but the change here was
7 to jack pine 60 per cent; poplar 40 per cent and,
8 therefore, even though both of these stands have mixed
9 species diversity and, therefore, the edge isn't very
10 sharp, there is a change in species and, therefore,
11 diversity created between the stands.

12 The same thing with age, where this may
13 be 30 years; both of these stands may be 80 years and,
14 therefore, while you have age diversity within these
15 stands you have very little age diversity between them
16 but you do have a sharp age diversity between these.

17 MR. FREIDIN: Q. Perhaps you could just
18 write a number 1 below the first stand that you
19 described and draw lines down below the stands -- just
20 put a number 1 below the stands which you described
21 first right at the top, and 2 and 3.

22 Mr. Chairman, perhaps we could mark that
23 as an exhibit.

24 THE CHAIRMAN: 463.

25 MR. FREIDIN: And my preference is to

1 title it: Diagram depicting forest diversity.

2 ---EXHIBIT NO. 463: Hand-drawn diagram depicting
3 forest diversity.

4 MR. FREIDIN: Q. Now, in that particular
5 drawing, Mr. Greenwood, am I correct that in terms of
6 genetic diversity or genetic variability that what you
7 have shown is a situation where genetic variability is
8 not different when you compare the genetic variability
9 within the stand to genetic variability sort of at the
10 forest level?

11 MR. GREENWOOD: A. That's correct.
12 Whereas the factors of species and age could vary both
13 within and between stands, the variability in what is
14 indicated as genetics is the same both within and
15 across or between the stands.

16 Q. And could you advise: Is there any
17 significance to this observation that genetic
18 variability is not different when you compared the
19 variability within a stand to the genetic variability
20 as between stands?

21 A. Yes. It is important in terms of the
22 effects that harvest could have on genetics in that
23 because the variability is the same over a much larger
24 area, an area that we define as a population, if in
25 fact you are harvesting at the stand level you aren't

1 affecting the variability at the population level.

2 Q. Now, throughout your evidence we are
3 going to be talking about the differences of diversity
4 I suppose in relation to age, species and genetics at
5 the stand level and at the forest level?

6 A. Correct.

7 Q. And in the diagram that you have
8 prepared up here you have simplified that and you have
9 shown three different stands.

10 In a very general way, what do you mean
11 when you use the term at the forest level when you are
12 making this comparison -- diversity within a stand as
13 compared to diversity at the forest level?

14 A. I do use the term throughout the
15 evidence quite frequently. In my mind I was thinking
16 that the forest is the area which is normally managed
17 and, as such, it could equate to a management unit. It
18 could equate to larger than a management unit as well,
19 but for purposes of this evidence it is probably easier
20 to think of it as that area for which management
21 objectives are set and, therefore, the management unit.

22 Q. Okay. What is the purpose of your
23 addressing this diversity?

24 A. The area that I addressed it under
25 are in fact the three important elements in the forest,

1 the diversity of which can be affected by harvest.

2 Q. Is there any particular significance
3 to this diversity?

4 A. Yes, there is. It's a generally
5 accepted principle that the more diverse the forest or
6 its organization, the greater that a variety of
7 benefits that can be produced from it.

8 It also reflects its ability to adapt and
9 survive under future environmental change, therefore,
10 this diversity is important for that, at the forest
11 level, for the forest to adapt and change.

12 Q. And when you say the ability to adapt
13 to changes in the future, would you be including in
14 that not only anticipated changes in the environment
15 but unanticipated changes?

16 A. I would probably emphasize the
17 unanticipated changes.

18 Q. Is this general or overall principle
19 or concept to diversity always true?

20 A. Well, I think it is always true at
21 the broad sense at the forest level or in a general
22 sense, but there is always specific species of wildlife
23 or plants or even segments of society which either
24 would prefer or even require that the diversity be
25 limited, particularly at the local level.

1 If I might give an example. In terms of
2 a species of wildlife there is a small warbler called
3 the Kirtland's warbler which requires for its nesting
4 habit a very specific habitat, it's young regenerating
5 jack pine, relatively open and on a drier site because
6 they nest on the ground. So in the case of the
7 Kirtland's warbler they require a very specific habitat
8 and in fact to satisfy their needs need that diversity
9 limited.

10 Another example would be a mill that can
11 only utilize jack pine. It may be that the most
12 beneficial diversity for that mill would be one limited
13 to only a jack pine forest.

14 And even a third example would maybe be a
15 recreationalist that only prefers to recreate in older
16 forests, so for that person their objective would be to
17 have older forests.

18 Q. Okay. So basically forest diversity
19 can be seen as positive by some people or be positive
20 for some species of wildlife or plant but, on the other
21 hand, be viewed -- the same situation be viewed as
22 negative by others depending on what are their
23 particular objectives or needs might be from the
24 forest?

25 A. That is correct.

1 Q. Referring to your paper, Mr.
2 Greenwood, in terms of forest diversity - and I am now
3 talking to all three kinds of diversity that you have
4 mentioned, the three aspects of forest diversity - was
5 it your intention to address the positive or the
6 negative aspects of forest diversity in terms of a
7 particular objective for the forest?

8 A. No, it was not. I specifically was
9 trying to look at it in the sense that limiting
10 diversity to meet specific needs or objectives, certain
11 products or even values is necessary but that that
12 should be done in the context of maintaining diversity
13 at that broader level.

14 Q. If management objectives result in
15 the conscious limiting of diversity at the stand level,
16 is it contradictory to say that this limitation of
17 diversity should occur within the context of forest
18 diversity in the broader sense is important?

19 A. No, I don't think it is. And I think
20 that there is three things that can be considered here
21 that might help explain that.

22 If I use natural disturbance as the
23 benchmark, the diversity can change at any point in
24 time following natural disturbance at the local level.
25 If a fire comes through, it can alter the disturbance

1 at the stand level as we've described it, but because
2 fire doesn't occur everywhere at the same time and in
3 the same way, diversity at the forest level is still
4 maintained.

5 And harvest, in some respects, is
6 comparable to the natural disturbance in this sense, in
7 that it doesn't take place everywhere at the same time
8 throughout the whole area of the undertaking and,
9 therefore, it can affect diversity at the stand level
10 but still maintain diversity at the forest level.

11 Foresters in consultation with wildlife
12 and fisheries biologists can utilize this concept to
13 meet the objectives of providing forest products, at
14 the same time as providing the benefits of diversity in
15 the larger sense.

16 So I think that is really the first major
17 factor that I would consider in looking at our ability
18 to achieve this and, in fact, I think you can look at
19 it as shuffling the deck but not changing the deck.
20 Forest management can alter where the cards are in the
21 deck, but still maintains the deck.

22 MR. FREIDIN: I am sure that analogy will
23 probably get us into discussions similar to the game of
24 checkers, Mr. Chairman. It will be interesting to see
25 what the analogies are.

1 MR. GREENWOOD: Now, a second
2 consideration that I would like to explain is the fact
3 that timber management only takes place on part of the
4 land base. There are still parks and reserves and
5 withdrawn areas that are not affected by timber
6 management and the significance of this fact is that
7 nature will take its course on these sites and,
8 therefore, the diversity which would normally be
9 created by nature will still be created in these areas.

10 And likewise, natural disturbances still
11 take place on a significant portion of the area of the
12 undertaking and still, therefore, have significant
13 effects on the diversity that is formed at the forest
14 level and the randomness that is created through
15 natural disturbance as opposed to harvest.

16 MR. FREIDIN: Q. I would like to deal
17 with each of the three types of diversity, one at a
18 time.

19 But before we begin, when you refer to
20 the effect of harvest on species diversity, age
21 diversity and genetic diversity, are you making any
22 assumptions regarding the manner in which regeneration
23 occurs after harvest?

24 A. Yes, I am. I have limited the
25 discussion here to regeneration through natural means.

1 Regeneration through artificial means and its effect on
2 diversity at these three levels is discussed in Panel
3 11.

4 Q. Okay. So if we could begin then by
5 dealing with species diversity, and the walk you took
6 the Board through a moment ago in that drawing, Exhibit
7 463, you referred to species diversity within a stand
8 and you pointed out the diversity between stands. And
9 could you explain how this diversity was created
10 through natural forces?

11 A. It's really, if you were to simplify
12 it, created through three factors at the stand level.
13 The first would be disturbance and its type, severity
14 and frequency at that level, and that can range from
15 one tree falling over in the Great Lakes-St. Lawrence
16 Forest and an advanced growth seedling taking its
17 place, right through to the effects of fire.

18 The second thing -- second factor that
19 would determine what came back would be the site itself
20 and the fact that some species are more readily
21 available to regenerate and survive and compete on some
22 sites.

23 So the soil characteristics, the aspect,
24 the local climate would all be factors of site which
25 would determine the diversity, in effect, those stands.

1 The last significant factor would be the
2 reproductive sources that are in fact at play on the
3 site whether it be roots or advanced growth or seed.

4 Q. Okay. What role could harvest play
5 in species diversity?

6 A. In terms of the three factors I just
7 described, it plays the disturbance factor and in
8 combination with those other two factors, site and
9 reproductive forces, would determine the future
10 diversity of the stand.

11 Q. Okay. Now, when we are discussing
12 species diversity, in this context is there any
13 difference between a disturbance by nature -- natural
14 disturbance in comparison to disturbance through
15 harvest?

16 A. When one considers all of the natural
17 disturbances there would be very little difference, but
18 if one looks at the majority of the area of the
19 undertaking which has been regenerated by fire, I think
20 there are two differences there worth noting.

21 And one would be that harvest can remove
22 the reproductive sources from the site, particularly I
23 am referring to seed here, where fire would not do
24 that.

25 The second one would be that harvest in

1 some circumstances -- in fact in many circumstances,
2 would be less of a site disturbance than fire and,
3 therefore, there isn't as much mineral soil exposure
4 and it also wouldn't remove advanced growth and this
5 could obviously affect future diversity, in that if
6 fire burnt all of the advanced growth, then -- and
7 harvest didn't, there would be a difference in
8 diversity or difference in species following the two
9 disturbances.

10 Q. You indicated in that answer that
11 harvest could affect, I guess, the reproduction sources
12 by removal of a source of seed. Is that something
13 which automatically happens after each harvest, or is
14 that something which could occur as a result of the
15 harvest?

16 A. No, it could occur.

17 Q. In what ways could harvest followed
18 by natural regeneration affect species diversity within
19 a stand?

20 A. Like natural disturbance, it could
21 increase or decrease or maintain the species diversity.

22 Q. Could you give me an example of each
23 of those situations where you could maintain or
24 increase or decrease species diversity as a result of
25 harvest?

1 A. Yes, I can. And, again, I would like
2 to emphasize that that is dealing with only natural
3 regeneration following harvest, not the effects of
4 artificial renewal.

5 In the first example, if it was a pure
6 poplar stand which was clearcut, the natural
7 suckering -- root suckering of that poplar would in
8 fact regenerate the stand and create a new poplar stand
9 with the same species diversity as the original, and I
10 am assuming here a pure poplar stand. So in this
11 respect, clearcut has maintained diversity of the
12 stand.

13 In a second example, if the poplar stand
14 now had a jack pine component and was growing on a
15 fresher site, a site with a little bit more moisture
16 than a dry jack pine site and only the jack pine is
17 removed from that site, the reduction in the jack pine
18 seed source and the prolific root suckering of the
19 poplar on that site would in fact, in most cases,
20 create a pure poplar stand coming back. If there was a
21 jack pine component it would be very slight.

22 And, in this case, due to the factors of
23 site and reproductive sources and the way the harvest
24 was carried out, you could decrease species diversity
25 within that stand.

1 If we use the same stand however and
2 there is an understory, such as the one that I drew in
3 area No. 1 or stand No. 1 of either balsam fir or black
4 spruce or both and you removed just the jack pine,
5 there would still be some poplar suckering, but that
6 advanced growth would have quite a jump, so to speak,
7 on the poplar suckering and would, in fact - if the
8 stand was opened enough - form a component in the new
9 stand. And, in this sense, although the species jack
10 pine is being replaced by balsam fir and black spruce,
11 you are still maintaining diversity.

12 So on the same site as the previous
13 example, you are now maintaining diversity where the
14 previous one decreased it, just depending on somewhat
15 richness of the site and the condition of advanced
16 growth.

17 Q. I'm just wondering, have you given an
18 example yet of increase in diversity?

19 A. Yes. An example of increase in
20 diversity would be a pure jack pine stand on a fairly
21 dry clearcut site or a site clearcut in the summer -
22 and I say that because a clearcut in summer would
23 create some degree of mineral soil exposure - but in
24 this example the jack pine site, if it is surrounded in
25 poplar or if there is any poplar at all component in

1 that stand, you will get invasion of poplar on to the
2 site. With some seed source remaining from that jack
3 pine and some mineral soil exposure you will get a
4 component of jack pine regenerating on the site as
5 well.

6 In this instance, the pure jack pine site
7 or stand could be replaced by a mixed jack pine/poplar
8 stand and would in fact reflect an increase in species
9 diversity at the stand level.

10 Q. Does an understanding of species
11 diversity and in particular how disturbance can affect
12 it, have any significance for timber management?

13 A. Yes, it does. Knowing what will
14 occur naturally on those sites through, for example,
15 those examples I just gave, you would know what the
16 future stand would look like and this would, of course,
17 relate to ability to know species/site relationships.

18 And knowing what the future site would
19 look like, examined against the timber and non-timber
20 values for the area, would allow you to make informed
21 silvicultural decisions for that site. And I am
22 thinking of an example where knowing what would come
23 back naturally and taking into account objectives, one
24 may make the decision to artificially regenerate the
25 site as opposed to allow the natural regeneration to

1 take place.

2 Q. Can you advise, Mr. Greenwood,
3 whether this knowledge and these objectives that you
4 have just referred would be reflected in a timber
5 management plan?

6 A. Yes, they would be reflected in Table
7 4.11, the silvicultural ground rules of a timber
8 management plan.

9 Q. And I think -- I didn't ask or advise
10 the Board to bring their copy of that, nor did I advise
11 the other parties. Perhaps we will just leave that, we
12 will come back to that after lunch and we will deal
13 with where in fact you might see that in a timber
14 management plan.

15 Now, what effect do these changes in
16 terms of species diversity at the stand level have on
17 species diversity at the forest level?

18 A. Well, the effect is that even if you
19 change the species at the stand level through harvest
20 there is a number of factors, in fact there is four
21 factors that I could describe, operating within the
22 forest that would still create species diversity at the
23 forest level.

24 The first would be that harvesting is
25 dispersed in space and time throughout the forest and,

1 therefore, you are only affecting species diversity in
2 small patches throughout the forest at one point in
3 time. This relates to the shuffling of the deck.

4 A second point would be that the choice
5 of harvesting system, including harvesting intensity
6 and logging method, varies and each of these can
7 influence the new forest which regenerates and would
8 influence it to varying degrees throughout the forest.

9 And probably one of the most key factors
10 is the fact that site varies throughout the area of the
11 undertaking and site is a very strong influence on what
12 will regenerate on that area. And, in some cases, at
13 its extremes, there is only one tree species which will
14 grow within the limiting factors of the site and,
15 therefore, will maintain diversity.

16 Q. Can you just give me an example. You
17 must have some particular example in your mind when you
18 say that?

19 A. Sure. If you look at moisture
20 regimes of sites, they range from very wet right
21 through to very dry and in the middle you have these
22 fresh and moist sites that I referred to once or twice.

23 In those fresh and moist sites almost
24 anything will grow, and particularly those sites tend
25 to be related to nutrient richness as well and almost

1 any species will grow there and, in fact, many species
2 usually do grow there in a mixture.

3 As you move to the extremes in terms of
4 the rigors of the site, either very wet or very dry, a
5 number of species which can survive and grow there
6 becomes very limited and at the extremes, at the very
7 dry sites in the area of the undertaking, really the
8 only species which grows there effectively is jack
9 pine. And in the very wet sites the only species that
10 survives and grows there effectively is black spruce in
11 terms of forest species.

12 Q. Okay.

13 A. A fourth point that I didn't get to
14 and that's the fact that natural disturbance is still
15 taking place across the forest and it is followed by
16 natural regeneration in most cases and is significant
17 and, therefore, can affect species diversity at the
18 forest level.

19 So I guess the point of these four
20 factors is that when you combine the different effects
21 of harvest at the stand level and those other effects
22 of site and natural disturbance, the mosaic of new
23 stands which is created is in fact similar in terms of
24 complexity to the original forest and, therefore,
25 diversity in terms of species is maintained across the

1 forest.

2 Q. Is this change in species diversity
3 positive or negative?

4 A. I think I have tried to distinguish
5 between the stand level and the forest level and it
6 would depend on whether you are examining it at the
7 stand level or the forest level.

8 Q. Can you explain why there would be a
9 difference depending on which level you were looking at
10 it?

11 A. Well, if you affect species at the
12 stand level but are not affecting the mosaic or
13 diversity across the whole area of the undertaking or
14 the forest level in particular, you can only evaluate,
15 in my mind, whether that has been a positive or
16 negative effect when you take into account the
17 objectives for management at the stand level and
18 whether you have obtained those management objectives
19 at that stand level.

20 Q. Can you give me an example of where a
21 change in species diversity of a stand brought about
22 because of harvest could be positive or negative
23 depending upon management objectives?

24 A. If I go back to the poplar/jack pine
25 stand which is a mixed stand and harvest only the

1 conifer and it regenerates as I suggested the first
2 time to pure poplar, harvest in this sense has reduced
3 species diversity at that stand level. And if your
4 timber management objective was to supply conifer and
5 there was no market for poplar, then in fact that
6 reduction in species diversity could be negative in
7 terms of that timber management objective.

8 On the other hand, if in fact the
9 creation of this young poplar within that stand through
10 suckering is within a stand where in adjacent stands
11 there is conifer content, particularly conifer content
12 that might be suitable for habitat for moose, then you
13 may have created an optimal situation where there is
14 ample browse next to habitat or cover and, therefore,
15 have created a positive effect in terms of a wildlife
16 objective.

17 Q. Let's just change the hypothetical a
18 bit and let's say that there was a poplar market in
19 that same situation, either existing or being
20 contemplated in the very near future for poplar from
21 that particular area; would the situation change?

22 A. In that respect the change in species
23 diversity would be positive for both objectives.

24 Q. Okay. And, Dr. Euler, do wildlife
25 managers have any input into decisions which are made

1 within timber management which can affect species
2 diversity?

3 DR. EULER: A. Yes, they do. They are
4 usually part of the planning process and they would
5 have in the back of their minds the various objectives
6 that they are working towards, and one of the goals
7 that they would often be working towards is increasing
8 the diversity of the plant communities there.

9 Q. And I understand we will probably be
10 dealing with that in much more detail after the break?

11 A. Yes, I believe so.

12 Q. Okay. Just dealing with the second
13 level or the broader level, species diversity at the
14 forest level, would a reduction in species diversity or
15 changes in species diversity be positive or negative at
16 the forest level?

17 MR. GREENWOOD: A. If it was in fact a
18 reduction in species diversity, I would consider it a
19 negative.

20 Q. Okay.

21 MR. FREIDIN: Mr. Chairman, that's a
22 convenient place to break. I am going to move on into
23 age diversity, so if we can break then and I understand
24 until two o'clock?

25 THE CHAIRMAN: That's correct, we'll

1 adjourn until two o'clock.

2 MR. FREIDIN: Thank you.

3 THE CHAIRMAN: Thank you.

4 ---Luncheon recess taken at 11:55 p.m.

5 ---Upon resuming at 2:00 p.m.

6 THE CHAIRMAN: Thank you, be seated.

7 MR. FREIDIN: Q. Just a couple of
8 questions of clarification before we get on to age
9 diversity.

10 Dr. Euler, this morning Mr. Greenwood
11 dealt with the effect that having objectives for
12 particular species of wildlife or a segment of society
13 could result in a particular species wanting a limited
14 diversity as opposed to diversity in terms of just
15 generally in the forest.

16 And I think he used an example of a
17 species of wildlife or plant that might require
18 specific needs in terms of diversity. He used the
19 example of a Kirtland's warbler, is that the right
20 way...?

21 DR. EULER: A. Yes.

22 Q. Now, I understand that you just
23 wanted to make a brief comment in relation to that
24 example?

25 A. Well, a Kirtland's warbler is a

1 perfectly good example of that phenomenon, however, we
2 don't have any of those birds in Ontario that nest here
3 and there are, however, a number of animals that
4 illustrate that principle that do live in Ontario.

5 A spruce grouse is another good example,
6 rough grouse is another good example of species that
7 don't require diversity as much as they do a certain
8 fairly uniform type of habitat.

9 Q. Okay. Mr. Greenwood, if I can go
10 back to the evidence you gave right almost at the
11 outset of species diversity. You were describing the
12 differences between harvest and natural disturbance in
13 relation to the subject matter of species diversity.

14 And I understand that you want to go back
15 and just make a couple of comments to ensure that there
16 was no misunderstanding or perhaps unintentional
17 misinterpretation of the message you were trying to
18 convey?

19 MR. GREENWOOD: A. Yes, it was just to
20 clarify a couple of comments that I did make or I think
21 I made. It may have been said that wild fire wouldn't
22 remove the seed source where harvest would, and the
23 assumption I was making there was that wild fire
24 wouldn't normally remove the seed source.

25 There are certainly circumstances where

1 wood - in fact I can think of two - if wild fire went
2 through a young fire regenerated jack pine stand which
3 wasn't old enough to be producing a cone crop yet or
4 just young enough that the cones were just starting to
5 form, it could in fact remove the cone crop the same as
6 harvest would.

7 A second one I think that I also referred
8 to was wild fire potentially creating more disturbance
9 than harvest and I think the reference was to the
10 forest floor. And, again, this is often the case, but
11 I would qualify it by saying that it would very much
12 depend on, if you were making this type of comparison,
13 the season of harvest, the type of logging method that
14 was used and, in terms of the fire, the severity of the
15 fire.

16 Q. And in terms of the exposure of
17 mineral soil due to the disturbance of harvest as
18 opposed to fire, how would you compare the two
19 disturbances?

20 A. In much the same way, that it would
21 depend on the severity of the fire and the season of
22 harvest. Fire would always affect the forest floor in
23 that it would always consume some of it, but it would
24 very much -- whether it exposed mineral soil, would
25 very much depend on the severity of the fire and the

1 thickness of the forest floor. In terms of harvest the
2 same thing would be true, it would depend on the
3 thickness of the forest floor and, in fact, the season
4 of harvest in this case.

5 Q. Okay. And we had a section in
6 species diversity where you were going to refer to the
7 timber management planning manual. I was asking you
8 whether an understanding of species diversity and, in
9 particular, how disturbance can affect it had any
10 significance for timber management.

11 And you said, basically knowing what
12 would occur naturally in terms of regeneration and what
13 species were likely to come back, foresters could use
14 that understanding and that knowledge to in fact make
15 silvicultural decisions.

16 A. Correct.

17 Q. Particularly if they wanted to change
18 what was going to come back. And you had indicated
19 that the timber management planning manual did have a
20 table in it which would indicate or manifest where this
21 type of knowledge might be reflected, and I think it
22 was Table 4.11 in Exhibit No. 7?

23 A. That's correct.

24 Q. And could you indicate what portion
25 of that particular table that you are referring to?

1 A. I am referring to three columns in
2 particular in this table which has been discussed
3 before.

4 Q. Just one moment, Mr. Greenwood.

5 MR. FREIDIN: Mr. Chairman, I can give
6 you a copy of our exhibit, of the Timber Management
7 Planning Manual. (handed)

8 THE CHAIRMAN: Thank you very much.
9 Sorry, what page again?

10 MR. FREIDIN: I think it is at page...

11 MR. GREENWOOD: 65.

12 MR. FREIDIN: 65, yes.

13 Q. All right. You said that you were
14 going to refer to three columns in that table?

15 MR. GREENWOOD: A. That's correct. The
16 far left column which says FRI WG or FRI working group,
17 two columns over which is PROP, proposed working group
18 or forest unit, and under the heading Stocking
19 Standards, the far right column, minimum to acceptable
20 species.

21 Now, if in fact - and in this situation
22 we were talking about natural regeneration - the forest
23 manager had a working group in the left column such as
24 poplar and the proposed working group was again poplar,
25 that in itself -- and the renewal treatment was natural

1 regeneration, that in itself is a manifestation of that
2 forester's knowledge that that site is naturally going
3 to root sucker back to poplar.

4 If in fact it was poplar but there was an
5 understorey of balsam fir or black spruce, you would
6 probably see under the proposed working group that
7 component forming part of the working group or forest
8 unit in the proposed working group, or you would
9 possibly see it reflected under the minimum to
10 acceptable species in that the balsam fir and black
11 spruce would be acceptable.

12 Q. And conversely, if you had a change
13 from the working group which perhaps was poplar in the
14 left-hand column and that you were proposing to in fact
15 change the working group, would you see a reflection
16 then again of that understanding?

17 A. Yes. If in the case where I think I
18 said you might have a jack pine and poplar current FRI
19 working group and the poplar could root sucker and the
20 proposed working group would be poplar then, knowing
21 that the silvicultural prescription may be for
22 artificial regeneration, site preparation and
23 artificial regeneration to keep the jack pine component
24 in the stand, and then depending on intensity of that
25 treatment your proposed working group could in fact be

1 again jack pine and poplar.

2 And it would be -- so the reflection of
3 what would have happened on the site would result in
4 the artificial regeneration treatment being applied.

5 Q. Okay, thank you.

6 MR. FREIDIN: Mr. Chairman, we'll be
7 seeing an entire Table 4.11 when we deal with the
8 timber management planning process in Panel 15.

9 THE CHAIRMAN: Do you need this back?

10 MR. FREIDIN: Sure.

11 THE CHAIRMAN: (handed)

12 MR. FREIDIN: Q. Okay. If we could move
13 on then to age diversity. Does harvest have an effect
14 on age diversity, Mr. Greenwood?

15 MR. GREENWOOD: A. Yes, it does.

16 Q. And can you describe what those
17 effects are?

18 A. Well, harvest like natural
19 disturbance, or at least harvest as a part of a
20 silvicultural system is the first step in renewal and
21 as such converts older stands into younger regenerating
22 stands or is an important phase in that component.

23 In uneven-aged stands, as we have heard
24 from Mr. Hynard, the selection harvest system can open
25 the canopy and in fact allow for advanced growth or

1 regeneration as a result of light entering that forest.

2 I think in earlier evidence by Dr. Osborn
3 in Panel 3 he described how many of the management
4 units in the area of the undertaking have skewed age
5 classes to the older -- or the age class distribution
6 is skewed to the older age classes. And this fact
7 combined with the fact that harvest is dispersed in
8 nature compared to fire can create greater spacial age
9 diversity throughout the area of the undertaking,
10 particularly in the boreal forest, by distributing this
11 age class difference over smaller areas.

12 Q. Now, as I recall the evidence of Dr.
13 Osborn in describing objectives of timber management,
14 he indicated that, at least at one portion, that the
15 objective was to provide a continuous supply of wood to
16 the forest products industry while at the same time
17 attempting to manipulate the forest into a normal
18 forest which would have equal age class distribution or
19 an equal area in all age classes over time.

20 Now, if that objective of normal forest
21 was achieved, what would that do for age classes
22 represented within each working group?

23 A. Well, within the normal forest the
24 age class is -- the area within each age class in the
25 working group would be the same, therefore, if you are

1 starting with a forest which is skewed to the older age
2 classes, you would create more area in those even-aged
3 classes but because the normal forest assumes that all
4 areas are harvested at rotation age, you could create
5 those -- the area in the younger age classes at the
6 expense of area in age classes above rotation age.

7 Q. In the normal forest you wouldn't
8 have age classes which would be overmature when
9 compared to rotation?

10 A. That is correct.

11 Q. Now, for the present working groups
12 do you foresee the disappearance of these older age
13 classes within the foreseeable future?

14 A. No, I don't. It is unlikely that it
15 would occur in less than a rotation for most of the
16 units or at least for many parts of area of the
17 undertaking. However, that would vary by management
18 unit, it would vary by species that you are examining
19 throughout the area of the undertaking.

20 Q. Can you put any geographic bounds on
21 where these management units might be the ones which in
22 fact have a preponderance of overmature?

23 A. The preponderance of overmaturity is
24 related to the degree to which we have been successful
25 in protecting the forest from natural disturbance,

1 therefore -- and I would have to say in a very general
2 sense, because I don't know that there is a trend where
3 I could identify a geographical area.

4 But in areas where natural disturbance
5 has played a larger role in regenerating the stands -
6 and I think it is generally accepted for instance in
7 the northwest fire incidence is higher in the northwest
8 region than the northern region - I would expect that
9 within that northwest region it would be a geographical
10 area which would move towards the normal forest quicker
11 than the northern region.

12 Q. Okay. You made a comment about that
13 it was unlikely that you would foresee the
14 disappearance of these older age classes, age classes
15 beyond rotation for at least a rotation in many areas,
16 as you say, depending on management unit and species
17 that you were talking about. Could you explain the
18 basis of that belief?

19 A. I think it's based in the
20 understanding that the normal forest is a concept, it
21 is a principle, it is a principle that allows us to
22 manage in a way that ensures best utilization of the
23 forest from a timber management perspective and, as
24 such, it really is a theoretical state and almost
25 impossible to attain at the forest level.

1 Now, there is three principal reasons why
2 I would say that. The first is that it assumes that
3 the entire maximum allowable depletion is in fact
4 depleted, and yet we know that markets and
5 accessibility and merchantability of stands that exist
6 normally results in the maximum allowable depletion
7 being at -- sorry, the actual depletion being less than
8 that maximum.

9 The second reason would be that it
10 assumes that cutting strictly follows the oldest first
11 principle, you must be removing timber from those
12 oldest age classes to move towards the normal forest.
13 But again we know that accessibility and
14 merchantability of many of these stands, particularly
15 those which are already into a very old state, and the
16 large preponderance of these older age classes now
17 within the area of the undertaking makes this
18 unrealistic in actual practice.

19 The other assumption within that
20 statement would be that the managed forest would have
21 to equal the total forest and, again, we know that
22 parks and private lands and withdrawals and certain
23 reserves don't form part of the managed forest and,
24 therefore, undergo the natural processes of aging.

25 So for the normal forest to exist is

1 almost impossible, particularly over the whole forest
2 within the undertaking.

3 Q. I would ask that you demonstrate
4 basically what you have said, and I understand that to
5 do that you want to refer to a number of histograms; is
6 that correct?

7 A. That's correct.

8 Q. All right.

9 MR. FREIDIN: And perhaps I could provide
10 copies (handed)

11 THE CHAIRMAN: How do you want these
12 numbered, Mr. Freidin?

13 MR. FREIDIN: Well, there are four of
14 them. I think we can just make them one exhibit, page
15 1, 2, 3, 4.

16 THE CHAIRMAN: All right. Exhibit 464.

17 ---EXHIBIT NO. 464: Series of four histograms.

18 MR. FREIDIN: 464, Mr. Chairman?

19 THE CHAIRMAN: That's correct.

20 MR. GREENWOOD: At first glance this
21 looks somewhat confusing, but I will explain how the
22 table is put together, these histograms are put
23 together and it should make more sense.

24 Across the bottom we have a series of age
25 classes from the NSR Classes 2 to 4, so those areas

1 which have not entered free to grow yet, and free to
2 grow to 20, 21-40, and so on up to 121 plus, and the
3 121 plus actually includes ages up to 150 in it.

4 These age classes are for an actual
5 forest, Superior Forest in Chapleau District. They
6 represent the spruce working group for that forest and
7 the age classes were generated as a result of a run of
8 AWOSFOP which generated the data necessary to put the
9 age class distributions together at certain points in
10 time into the future.

11 The solid black lines across the front
12 are the current areas within each one of those age
13 classes, so age class distribution of the current
14 forest.

15 As you move back behind that first column
16 you are going back 20 years in time with each step back
17 towards the back of the histogram. So, for instance,
18 20 years into the future -- I should back up. Each
19 step in time harvest takes place and the assumption in
20 this case was that which - one of the conditions I
21 mentioned a minute ago - a hundred per cent of the MAD,
22 and one of the other factors that would affect age
23 class distribution is that of regeneration.

24 Obviously if you are harvesting in one
25 working unit or forest unit or working group but moving

1 that area into another, converting it to another
2 species, it is not coming back in at the bottom end and
3 you could skew your age class distribution so the
4 average age is older. But it is not really an effect
5 of actual -- of changes that would go on.

6 Now, in order for the normal forest to
7 take place, what we are going to examine is the effect
8 of a hundred per cent maximum allowable depletion
9 taking place and you will notice that in this forest
10 the oldest age class 121 plus exists for over 60 years
11 into the future; 20, 40, 60 years we still have an area
12 within this working group before it then drops to a
13 younger age class and then this working group does not
14 exist any more within -- and we move towards the normal
15 forest.

16 Just a little easier way to see this. If
17 you in fact are harvesting oldest first, you are
18 harvesting where there still is area of age class
19 distributions and this is the same thing just showing
20 where each five year, the age of the five-year MAD and
21 where it is coming from. So again you see that in fact
22 it drops down to fairly young age class before it -- in
23 the 81-100 year before it comes back after close to
24 hundred years where all the harvesting is taking place
25 at rotation age.

1 MR. FREIDIN: Q. So if we look at
2 that -- we look at 121 plus, that oldest age class
3 continues to exist for 80 years?

4 A. That's correct.

5 Q. And after -- and during those 80
6 years --

7 A. Within the hundred year run the age
8 class of the oldest stands within this forest unit is
9 now in the 81-100 year class and then the following
10 20-year period, 120 years from now it would still be in
11 that age class before it comes back up to the 101-120
12 age class, the rotation age - I neglected to mention
13 for this species is 110 years - so you are reaching,
14 you are close to your normal -- or at least you are
15 harvesting that rotation age only after 120 years of
16 harvesting.

17 Q. Okay.

18 A. Now, the purpose of this was to he
19 show how if you didn't harvest just full MAD, which was
20 one of the three factors, how that could change what
21 happens to your age class distribution.

22 So the next run was made where only 60
23 per cent of the MAD is harvested.

24 Q. And this is again for the Superior
25 Forest and is spruce?

1 A. Same forest same data set up the same
2 way in terms of runs into the future.

3 Q. Right. And the document that you are
4 referring to is that part of the exhibit which is
5 entitled Spruce B2.

6 A. That's correct. Now, because you are
7 not harvesting the full MAD there are still areas in
8 this older -- in these older age classes which remain.
9 You are not removing all of that area and, therefore,
10 moving into the younger age classes towards the
11 rotation age which would take place when you reach the
12 normal forest.

13 And in this case for the full extent of
14 the run, 140 years, you still have area within the
15 oldest age class in this particular model which might
16 be 121-150 years, or in the case of where your
17 harvesting is coming from, the age class of the stands
18 from where your harvest is coming from --

19 Q. And now you are referring to the
20 fourth page of this exhibit which is entitled Spruce
21 B1?

22 A. It always takes place in the 121 plus
23 age class. So just by reducing -- reflecting the fact
24 that the full maximum allowable depletion was not
25 taking place, you have created a forest where you are

1 always harvesting well above rotation and old age
2 stands continue to exist.

3 If you combine just that one factor with
4 the other two factors, in fact you would create a
5 situation where there is even more forest in the
6 121-150 age class.

7 Q. And are there working groups in
8 various management units which are being harvested at a
9 rate less than a hundred per cent of the maximum
10 allowable depletion for that working group?

11 A. Yes, there are.

12 Q. And I take it there are working
13 groups of the various types where in fact, depending on
14 management unit, you may be harvesting close to the
15 MAD?

16 A. Yes.

17 Q. All right. And that basically goes
18 to your comment earlier that the situation would vary
19 by management unit and by working group?

20 A. That's correct.

21 Q. Okay.

22 A. In terms of the relationship, it
23 would be almost a straight line relationship. If in
24 fact you were harvesting 80 per cent, you would in fact
25 maybe move towards normal; in the hundred per cent it

1 was after 80 years, it might be after 120, 140 years
2 that you would get to normal.

3 Q. All other...

4 A. Or rotation age I should say.

5 Q. All other variables remaining
6 constant?

7 A. Correct.

8 Q. Genetic diversity, perhaps we can
9 move on to that now. I understand that before we
10 really get into this you would like to begin this
11 discussion by describing certain basic concepts which
12 you feel should be understood?

13 A. That's correct.

14 Q. And can you describe those concepts?

15 A. First of all, when we examine genetic
16 diversity it can be discussed at three different
17 levels: It can be discussed at the level of the
18 individual tree, it can be discussed at the stand level
19 or at the population level, but when you are doing
20 so -- when you are discussing it at any one of those
21 levels, there is three important concepts that you must
22 keep in mind. And I don't intend to elaborate too much
23 on these concepts, some of them will be the basis of
24 evidence given in Panel 11.

25 The first one is that genetic variability

1 is necessary in a population, and that is as opposed to
2 a tree or a stand, to ensure that that population can
3 reproduce and maintain itself in a changing environment
4 over time.

5 Q. Could you describe what you mean by a
6 population?

7 A. Population. Well, a population, it
8 would vary. What I mean by population would not vary
9 but the actual geographical bound of it would vary by
10 species. But in simple terms it is simply the area --
11 an area where interbreeding of individuals takes place.

12 Q. And is that a large area, a small
13 area - and, again, I know I am asking you to
14 generalize - but just to understand your evidence
15 without getting into all the sort of scientific details
16 of this, can you give some idea of what you are talking
17 about in terms of area?

18 A. With our species in the area of the
19 undertaking, the major ones we are looking at, it is a
20 relatively large area in that our pollen can fly over
21 200 miles and, therefore, it can be fertilizing cones
22 or female flowers that are a long distance away. So
23 that population can be quite large.

24 Now, there are exceptions to that. If
25 you had an area where -- of a particular species which

1 was separated by a particularly large distance from
2 others of that species and that -- the area of that
3 species where it was separated was quite small, it
4 could form its own interbreeding population.

5 Maybe an example is the easiest way to
6 explain that. When you move into the Clay Belt area,
7 the presence of jack pine is reduced fairly
8 dramatically and poplar and black spruce is very, very
9 common.

10 North of Kapuskasing there is a pocket of
11 soil that is appropriate for jack pine and there is a
12 fair amount of jack pine in that area. That jack pine
13 however is far enough away from other stands of jack
14 pine that I would consider it a separate population of
15 jack pine. It may or may not be, one would have to
16 test, but for purposes of management, I would consider
17 that a separate area.

18 The other thing with population, now that
19 it has been opened, we tend to draw lines around a
20 population for purposes of discussing it or managing
21 but, in actual fact, a population wouldn't have --
22 wouldn't usually have strict boundaries. In the case
23 of the isolated population it could have a fairly
24 definite boundary, but in a species such as jack pine
25 that ranges all the way from Newfoundland to Alberta

1 there is a lot of interbreeding all the way along.

2 In other words, there is a gradient and
3 for purposes of management we would draw lines around
4 areas and, in fact, there definitely throughout that
5 area would be differences in the way the species would
6 respond to various effects of the environment.

7 In fact Mr. Armson led or described
8 briefly the clinal variation that latitude creates as
9 one moves north, I think he used red maple. Red maple
10 grows in Florida and grows at the northern end of the
11 area of the undertaking. As you move throughout that
12 clinal variation, that tree would have different habits
13 of bud set and bud break that would be related to the
14 environment that it is growing in and it would be
15 difficult to draw lines and you wouldn't find a place
16 where it flushed one week here and, as you crossed the
17 line, it flushed the next week. There would be a
18 gradient.

19 Q. Okay. And just to deal with that
20 isolated population of jack pine near Kapuskasing, in
21 the area that you are talking about would that be an
22 area smaller than a management unit?

23 A. Yes, it would be. In most cases the
24 populations that we are talking about would be larger
25 than a management unit.

1 Q. Okay. Now, I think that is one of
2 the three concepts that genetic variability is
3 necessary in a population to ensure it can reproduce
4 and maintain itself.

5 A. That's correct.

6 Q. What are the other two?

7 A. The second one that is important to
8 understand - and I think it came up briefly - when I
9 drew the drawing and talked about genetic diversity on
10 the flip chart, I talked about -- you could see
11 indications of the genetic makeup of those trees.

12 What we actually see is not the genetic
13 makeup of the tree or its genotype, what we see is an
14 interaction between the genotype and the environment
15 that it has grown up in and the term that we use to
16 describe that is its phenotype. In other words, there
17 are genes controlling the way that tree is growing and
18 how it looks, but the environment can also affect the
19 way that tree looks and how it grew and that is what
20 you see.

21 Now, given that there are certain
22 characteristics of trees that we know are fairly
23 strongly controlled by genetics and, therefore, when we
24 see that particular form or characteristics we are
25 relatively sure that what we are seeing is a

1 manifestation of the genetic makeup of that tree.

2 In jack pine, stem form is one, for
3 instance

4 Q. All right. And the third concept?

5 A. The third concept is that genetic
6 variability does change naturally, and probably one of
7 the most visible examples of that would be the natural
8 selection that takes place within the forest.

9 Mr. Hynard, when he was leading his
10 evidence, made the comment that I think it was one
11 stand was 13,000 stems per acre and that it would end
12 up at maturity at about 400. Something is happening to
13 those stems and that is the process of natural
14 selection whereby they are competing with each other
15 even though they are the same species and some will be
16 winners and some will be losers. I think this is
17 commonly referred to as survival of the fittest.

18 So in doing that, the genetic variability
19 or diversity within the stand is in fact being reduced
20 naturally in that the so-called losers are dropping
21 out.

22 Q. What is the significance of these
23 concepts in relation to harvest activities?

24 A. Probably the easiest way to do that
25 is to go back through them and talk about them from a

1 harvest perspective.

2 Q. All right.

3 A. The first one was the concept that
4 genetic variability is necessary at the population
5 level and the significance of that is that harvest
6 which takes place at the stand level can affect genetic
7 diversity at the stand level but that foresters would
8 be concerned with maintaining the diversity at the
9 population level. Therefore, even though you had an
10 effect at the stand level, that may not be affecting
11 the variability at all at the population level.

12 Q. Could you provide an example of how a
13 concern by a forester about genetic variability in the
14 population could be manifested?

15 A. I am not sure if evidence has been
16 led about seed control zones yet, but one of the things
17 that represents that type of concern would be the
18 designation of areas within which seed must be
19 collected and, particularly for the regeneration
20 program, any regeneration which takes place must be
21 utilizing seed from within that zone.

22 So it is an approximation of a
23 population. If you are going to regenerate
24 artificially within that area you must use seed which
25 is collected from within that seed zone. We control

1 movement of seed therefore to within populations.

2 Q. Okay. Now --

3 A. Sorry.

4 Q. Go ahead. Could you deal with the
5 second concept then?

6 A. The second concept related to the
7 fact that what we are seeing is in fact phenotype as
8 opposed to genotype or we are seeing characteristics
9 which may or may not be a reflection of the genetic
10 control that is taking place within that particular
11 species.

12 The results of operations therefore,
13 particularly those which might select for certain
14 characteristics, may or may not be affecting the
15 genetics; they would only be affecting genetic
16 diversity if in fact those characteristics selected for
17 were in fact characteristics -- were reflections of the
18 genetic makeup of that individual.

19 In either case, if those -- if that area
20 was regenerated from individuals which were genetically
21 related to those removed there would still not even be
22 an effect at the stand level.

23 Q. Okay. Mr. Hynard, would you be able
24 to provide an example of where -- of the second concept
25 in practice?

1 MR. HYNARD: A. When Mr. Greenwood was
2 talking about variability between trees and genotypes
3 and phenotypes, I was thinking about a tree marking.
4 When we are marking trees for selection cutting or for
5 commercial thinnings or improvement work, a tree marker
6 is faced with decisions tree-by-tree. He is making
7 choices about which trees to take and which trees to
8 leave and, of course, he is forced to look at the
9 variations in trees and all he knows about the tree is
10 what he can see.

11 For example, if a tree has a crack and a
12 seam and it is rotten inside, he can see that. Is that
13 tree defective because it inherited that
14 characteristically or is it defective because of bad
15 luck, another tree fell on it when it was younger and
16 the wound became infected. And that is the kind of
17 thing that we see day-by-day and, of course, that tree
18 marker isn't certain about that at all.

19 He marks that defective tree to be
20 removed, not in order to improve the overall genetic
21 makeup of the forest, but rather because he knows that
22 rotten tree is just going to grow into a bigger rotten
23 tree and that is all the logic he really needs, unless
24 it has a value for some other purpose.

25 THE CHAIRMAN: Sounds like crime in the

1 forest.

2 MR. HYNARD: Anyway, if we continue to
3 harvest trees in that fashion, continue to remove trees
4 because they are slow-growing trees, low-vigor trees,
5 defective trees, are we improving the genetic makeup of
6 that forest in the long run. And I believe that not
7 necessarily, because that is a large breeding
8 population, we're not even certain that the
9 characteristics upon which we are selecting our
10 genetically controlled.

11 In the same way that I don't believe the
12 last 50 or 60 or 70 years of high-grade logging on my
13 unit, taking only the best and leaving the poorest, has
14 necessarily caused a degradation in genetic quality of
15 that population.

16 THE CHAIRMAN: Isn't a lot of that, Mr.
17 Hynard, to some extent better determined in the lab
18 setting where the nurseries are looking into putting
19 together the components of a better tree genetically?

20 MR. HYNARD: I don't know the answer to
21 that. I don't know if it is possible to determine, in
22 a laboratory, if a certain characteristic is inherited
23 or the case of bad luck. But, in most cases, we are
24 not working in a laboratory we are working in the
25 forest anyway, so...

1 THE CHAIRMAN: No, but aren't a lot of
2 nurseries trying to develop trees with various
3 characteristics that they believe--

4 MR. HYNARD: Yes.

5 THE CHAIRMAN: -can be better suited to
6 particular sites or areas or disease resistant and
7 things like that?

8 MR. HYNARD: Yes, that is true. There
9 will be evidence on that in Panel 11.

10 MR. FREIDIN: That is basically I think
11 referred to as the Tree Improvement Program?

12 MR. HYNARD: That's right.

13 MR. FREIDIN: Q. All right. Now, I
14 think the third concept which you described was how
15 through nature there was a natural selection or a
16 survival of the fittest within the stands over time.
17 And what is the significance of understanding that
18 concept in relation to harvesting purposes?

19 MR. GREENWOOD: A. Well, understanding
20 that genetic diversity can reduce within a stand over
21 time through natural selection, reflected in a timber
22 harvest which is planned and carried out to do a
23 similar thing.

24 Mr. Hynard just talked about removing
25 poor individuals from a stand. If in fact those

1 individuals are removed in a way that is analogous to
2 natural selection, and I think it is generally referred
3 to, an improvement selection cut, then the effect in
4 the long term would be the same as that through natural
5 selection within that stand.

6 If in fact you harvested in that way it
7 could almost be seen as long-term gain for short-term
8 pain in that you are removing poor individuals as well
9 as good individuals and you might prefer just to take
10 the good individuals.

11 THE CHAIRMAN: Isn't that the effect
12 essentially of your thinning program, your tending
13 program.

14 MR. GREENWOOD: The tending program can
15 select on that basis, but it wouldn't necessarily. The
16 thinning program is aimed more at providing more light
17 and space and nutrients for those trees which remain
18 and, therefore, allow the growth to go on to those
19 stems as opposed to the many.

20 But since you are removing individuals
21 anyways, you would normally select the better
22 individuals to leave and, in fact, possibly speed up
23 the natural selection process. And, again, this all
24 hinges on whether what you are seeing is in fact
25 genetics as opposed to just the effects of climate.

1 MR. FREIDIN: Q. You have indicated that
2 harvest through the use of a selection harvest or part
3 of the selection system is similar to survival of the
4 fittest which occurs through natural means, but are
5 there differences that you could comment on?

6 MR. GREENWOOD: A. There are
7 differences. Natural selection does not select on the
8 basis of economic traits; natural selection works on
9 the basis of the ability of the remaining trees to
10 reproduce and to survive and to compete.

11 Harvest does select or can select on
12 the -- well, it always does select on the basis of
13 economic traits, it may be selecting the poorer ones
14 out, but if it is poor it is poor on the basis of
15 economic traits, and if the selection in fact
16 corresponds -- if the fitness corresponds with fitness
17 in terms of the ability of those trees to reproduce and
18 survive in the environment, then the change that would
19 take place within that stand would be one that would be
20 similar to natural selection.

21 If, however, those economic traits were
22 not reflective of those traits which allowed the trees
23 to survive and reproduce in the environment, then it
24 would be in fact a different effect on genetic
25 diversity within that stand.

1 Q. So if your harvest reflects or
2 selects the same as would occur through natural
3 selection, you have got a similar result in terms of
4 the genetics?

5 A. That's correct.

6 Q. What does the phrase disgenic
7 selection mean?

8 A. Well, disgenic selection is strictly
9 a term to represent that practice where you -- what you
10 are selecting does not reflect what nature would have
11 selected.

12 Q. So in that situation then, if your
13 selection for economic criteria was a selection of
14 trees which wasn't the same as what would occur in that
15 stand naturally, that would be referred or the choice
16 within the harvest decision would be referred to as
17 disgenic selection?

18 A. In a general sense, yes.

19 Q. Where you have disgenic selection,
20 could that have a significant negative effect
21 genetically?

22 A. Yes, it could.

23 Q. In what situations could that occur?

24 A. Well, there is actually four points
25 that you would have to consider to determine whether it

1 in fact was occurring.

2 If you selected the individuals on the
3 site based on their quality and removed the good
4 individuals and left poor individuals on the site, but
5 at the same time left other genetically related
6 material, a material related genetically to the good
7 trees on the site, for example through advanced growth,
8 you would not have created a situation where genetic
9 diversity would be reduced.

10 So that's the first thing: Have you left
11 any genetically related material on the site, and that
12 could be through root suckering or stump crop as seed,
13 advanced growth or even younger trees of the same
14 species that were related.

15 It could also only occur if in fact this
16 selection was carried out across the whole population
17 in a relatively short period of time; that is, if
18 genetically related material from elsewhere in the
19 population was able to invade the site that had been
20 selectively harvested or had the better material
21 removed either through pollen or through seed, then
22 there wouldn't be loss of that material on the site and
23 definitely not within the population.

24 Also, one of the other factors that we
25 have mentioned one or two times is that the criteria --

1 the selection that you are using is based on phenotype
2 and that phenotype would have to be related to
3 genotype. If you were selecting based on quality and
4 the reason that those trees were of a higher quality
5 was strictly related to climate, you would not have
6 affected the genetic diversity even at the stand level.

7 And another criteria, if you were in fact
8 selecting these higher quality trees within this stand,
9 it would have to be intense, you would have to be
10 removing all of the good quality trees and, in most
11 cases, it would have to be repeated as well in order to
12 have affected genetic diversity negatively.

13 Q. Now, if through -- if genetic
14 diversity has been reduced negatively, is there any
15 ability of a species to recover from that reduction in
16 genetic diversity?

17 A. Yes, there is.

18 Q. Can you explain again when that can
19 occur or -- all right.

20 A. Well, it is not so much when, it is
21 based on the fact that trees have great inherent
22 genetic diversity within them and they also go through
23 a very heavy natural selection process after they have
24 seeded into an area and, therefore, when the trees
25 sexually reproduce, there is the chance that because of

1 the diversity within their genes they will reproduce a
2 good tree again.

3 So even two poor trees are carrying
4 characteristics of the better quality trees and through
5 sexual reproduction can produce a tree of the higher
6 quality and, therefore -- and when that -- that
7 combined with the fact that heavy natural selection
8 will favour that tree creates the situation over a long
9 term, better quality trees could form part of that
10 stand again.

11 Q. Okay. Mr. Greenwood, I understand
12 that you have some slides that you would like to show
13 and these are going to basically be demonstrating some
14 of the matters that you have testified to; correct?

15 A. That's correct.

16 MR. FREDIN: Now, if I just might, Mr.
17 Chairman, I think this is primarily for the assistance
18 of the exhibit keeper, the way these photographs are
19 going to go in is a little confusing so I would like to
20 explain what we are going to give you.

21 First of all, the list of photographs
22 which are reproduced in the witness statement are found
23 at page 208 to 212 and there you will find the pictures
24 and a brief description -- pardon me, you will find a
25 brief description of those pictures at pages 208 to

1 212. There are 53 pictures described.

2 Commencing at page 278, you will find
3 copies of the actual photographs. Mr. Greenwood will
4 not be showing all of the photographs, primarily
5 because some of them relate to subject matters which
6 were not addressed by him but rather had been moved
7 back into Panel 9 and were addressed by Mr. Armson.

8 I can advise you now, and the parties,
9 that the following photographs will not form part of
10 the presentation today and those photographs are 1, 4,
11 5, 6 --

12 THE CHAIRMAN: Are you working off of the
13 actual photographs or the list?

14 MR. FREIDIN: The actual photographs and
15 the list should correspond.

16 MR. GREENWOOD: They correspond.

17 MR. FREIDIN: In fact, Mr. -- so 1, 4, 5
18 6, 12, 13, 14, and 50.

19 MS. SWENARCHUK: Five zero or five one?

20 MR. FREIDIN: Five zero. Now, what I am
21 going to give to you, Mrs. Koven, is an envelope which
22 contains - with an exception which I will explain to
23 you in a moment - copies of the photographs which will
24 be shown today in the slide presentation taking out the
25 ones that I have just referred to.

1 with species/site relationships.

2 You will be talking about other things
3 those photographs demonstrate, but primarily that's the
4 main reason for producing them, and the slides which
5 fall into Category A are 7, 8, 9, 10, and 11.

6 THE CHAIRMAN: They are going to be shown
7 in that order?

8 MR. FREIDIN: They will be shown in that
9 order and I am not paying Mr. Greenwood anything for
10 repeating the numbers.

11 Category B is erosion. The slides which
12 fall into that category are the following, and in this
13 order: 15, 3, 16, 17, 18, 35, 36, 37, 38, 39, 40, 41,
14 42, 43, 44 and 45. I sound like I am announcing the
15 Wintario numbers.

16 Now, No. 15, Mrs. Koven, the hard copy of
17 that is not included in the package I gave to you, it
18 is in Toronto and we will provide a copy to you.

19 Category C, compaction and rutting. The
20 following slides will be shown: 2, 20 through 25
21 inclusive, 19, 26, 29, 27, 28, 30 through 34 inclusive.
22 And the slides in that package which are in Toronto and
23 aren't part of the hard copy which I have given to you
24 are -- and, Mrs. Koven, I don't know whether you have
25 to make copies of these, what we have done is we have

1 Now, the order in which those slides
2 appear in the actual hard copy I have given you and the
3 order which will be followed in the presentation does
4 not follow the order which is set out in the witness
5 statement.

6 THE CHAIRMAN: It makes perfect sense to
7 us.

8 MR. FREIDIN: That has occurred because
9 some of the photographs which would have appeared as
10 No. 1 -- you explain it, Mr. Greenwood, it drives me
11 nuts. Explain why you have moved the numbers around to
12 make things difficult -- other than to make things
13 difficult.

14 MR. GREENWOOD: Some of the photographs
15 which originally pertained to the topics which were
16 moved into Panel 9 were going to be used to demonstrate
17 points also in evidence that I led. So the only way to
18 put any sort of order to it was to move them into the
19 topic now which was being discussed as part of this
20 evidence.

21 MR. FREIDIN: Okay. Now, the slides
22 which will be presented fall into four categories and
23 Mr. Greenwood will be identifying when he is going from
24 one category to the other, but just so we know in
25 advance where we are going, let me say Section A deals

1 inserted a piece of paper in the right order with the
2 number of the photograph that you are going to get -
3 but they are, compaction and rutting section: 20, 21,
4 19, 26, 29, 27, 28, 30 and 31. That's the order in
5 which they will appear once you get your copies.

6 And the last section, Section D, deals
7 with diversity and those photographs or slides, all of
8 which are in the envelope, 46 through 49 inclusive, and
9 51 to 53 inclusive.

10 MS. SWENARCHUK: And the topic?

11 MR. FREIDIN: And the topic in a very
12 general way is diversity, forest diversity. And, as I
13 have indicated, some of those photographs are being
14 spoken to for more than one purpose, but generally that
15 is the categories into which they fall.

16 So with that introduction, I suppose we
17 could either turn out the lights and show the
18 photographs, or if you have any other views as to what
19 we should do at this particular stage, Mr. Chairman,
20 I'm all ears.

21 THE CHAIRMAN: Should we give it an
22 exhibit number?

23 MR. FREIDIN: I leave it up to you as to
24 how we should mark that as an exhibit.

25 THE CHAIRMAN: Exhibit 1,000.

1 MR. FREIDIN: Let's go, let's go.

2 THE CHAIRMAN: I think we are up to 465
3 and I guess we can call the photographs collectively
4 Exhibit 465 and then refer to them in the order in
5 which they will be shown.

6 MR. FREIDIN: I think by the number that
7 corresponds to the number in the witness statement.

8 THE CHAIRMAN: Right.

9 MR. FREIDIN: Okay. I think that's the
10 best way otherwise people who don't have the hard copy
11 will have difficulty understanding which picture we are
12 looking at.

13 THE CHAIRMAN: But in the order that they
14 are going to be shown; is that correct, because you are
15 not going to show them in the order they necessarily
16 appear in the witness statement?

17 MR. FREIDIN: No, they are going to be
18 shown in the order of the numbers that I read to you.
19 They are numbered in the witness statement, so all I am
20 saying is the first -- I think I know what your problem
21 is. The first slide is going to be slide No. 7.

22 THE CHAIRMAN: That's right.

23 MR. FREIDIN: And I think that should
24 just -- we should probably just mark the exhibit as
25 being whatever number it was and saying this exhibit is

1 composed of the following slides, the numbers of which
2 correspond to the numbers in the witness statement in
3 the following order and then reproduce 7, 8, 9, 10,
4 11, because when he shows the picture -- the slide, I
5 think he is going to say I am showing you slide No. 7.
6 So that's how I suggest that we do it.

7 There may be -- I wouldn't be surprised
8 if there is an easier way of doing it, I just can't
9 think of it at the moment.

10 ---Discussion off the record

11 THE CHAIRMAN: All right. Mr. Martel is
12 suggesting, why don't we say that they are all 465 but
13 then for each particular one it would be 465(7), for
14 instance.

15 MR. FREIDIN: Sure.

16 THE CHAIRMAN: Then that will correspond
17 with what is in the witness statement.

18 MR. FREIDIN: I think you are doing
19 basically what I have suggested, Mr. Chairman, which is
20 just adding...

21 ---EXHIBIT NO. 465: Hard copy of photographs
22 contained in Statement of
23 Evidence for Panel 10 (page
278-293) numbered respectively.

24 THE CHAIRMAN: Okay.

25 MR. FREIDIN: Are we going to show those

1 now? How long do you think that will take, Mr.
2 Greenwood?

3 MR. GREENWOOD: Probably three quarters
4 of an hour or less.

5 THE CHAIRMAN: All right. Why don't we
6 go through the slides now, then break before we go on
7 with Mr. Clark.

8 MR. FREIDIN: Okay. Can somebody turn
9 out the lights, please.

10 MR. GREENWOOD: What I thought I would do
11 is start by showing five slides that demonstrate some
12 of the points that we talked about, particularly when
13 we were discussing rutting and compaction and erosion
14 and that's the relationship between vegetation and the
15 site and the fact that you can get an indication of
16 site by looking at that vegetation that is in existence
17 on the site.

18 MR. FREIDIN: Q. Just one moment,
19 please, Mr. Greenwood. I know you are not going to
20 announce the numbers and I have lost my sheet.

21 MR. GREENWOOD: A. Slide No. 7, Mr.
22 Freidin.

23 Q. Well, I have lost the sheet so I am
24 relying totally on your ability to number the number.

25 A. Then it will cost you a dollar.

1 to a person examining this vegetation to get an
2 indication of site that we are on a relatively rich
3 site, it more than likely has a fine texture, or if it
4 is not a fine texture, then moisture is high in the
5 soil for some other reason. The duff layer on this
6 site is probably relatively thick, 10 to 15 centimetres
7 thick, there is a lot of material which will be adding
8 litter to that layer.

9 He would consider the fact that you have
10 a heavy root mat in terms of the shrub layer that's
11 there as well as the canopy layer, and all of these
12 things have ramifications for those topics of
13 compaction and rutting and erosion. If you remember
14 some of the key factors that we were looking at were
15 soil moisture, soil texture.

16 Q. Could you indicate what is it about
17 what you would observe in that slide which would
18 indicate that you were on a rich site?

19 A. It would be all of the factors that
20 I have just listed. The mixture of canopy species
21 would indicate that. Poplar will grow on low nutrient
22 status sites, but particularly when it is in a mix like
23 this with a strong undergrowth and understory advanced
24 growth, they would all be indicators that you were on a
25 relatively nutrient rich site.

1 This stand is a mix in the overstorey of
2 jack pine. You see the jack pine here and aspen,
3 poplar. The trees, if you were walking into the site
4 and trying to get some indication of what was going on
5 with moisture and soil texture, you would notice that
6 those trees are fairly large.

7 The gentleman standing beside the
8 poplar -- or, sorry, the jack pine would give you some
9 scale that that's, for jack pine, is a relatively large
10 tree. There are also relatively large -- and when I
11 discuss these indicators of site, I am not attempting
12 to do so in a quantitative way, it is relative.

13 The other thing that you would notice
14 immediately moving on to this site is that there is a
15 thick understorey of vegetation, in fact the gentleman
16 would probably have to battle his way into that tree.
17 It would be alder and hazel, possibly striped maple in
18 this understorey. You would also notice the presence
19 of advanced growth within the understorey, we have some
20 balsam in this understorey.

21 And one of the other things that a
22 forester would be noticing is that as well as the
23 shrubby undergrowth there is a herbaceous undergrowth
24 in this understorey.

25 Now, all of these things would indicate

1 Now, we talked about diversity as well
2 and you can see in this stand that it very much
3 represents the stand No. 1 that we walked into. There
4 is an overstorey with two species and, therefore, we
5 have diversity in that overstorey. We also have
6 younger trees in the understorey in the form of
7 advanced growth so we have age diversity within this
8 stand.

9 And if you look carefully you can also
10 see small and large jack pine. There is a small jack
11 pine compared to this large one. That may be a
12 reflection of genetics, it may be a reflection of
13 competition that that smaller jack pine has had from
14 the poplar.

15 Now, on the next site, this is slide No.
16 8, you would notice that there is still a mixture of
17 overstorey species although it is more difficult to
18 see. There is poplar in the background in here, but we
19 now have a far higher component of jack pine. That in
20 itself would tell us that we have moved on to a
21 somewhat drier site. When we look at the understorey,
22 you will notice that the shrub layer is not as tall. it
23 is not as thick or as prolific. and that also will be
24 an indication of a less nutrient rich site and probably
25 a drier site.

1 In terms of the potential for rutting,
2 the last site, because it would be finer texture and
3 have a higher moisture content, would be one of those
4 sites which could be rutted under certain conditions.
5 If that last site had a high moisture content for
6 instance in the spring, it would more than likely be
7 susceptible to rutting. This site would be less
8 susceptible and you really couldn't determine if it was
9 or wasn't until you checked the soil.

10 In terms of an undergrowth, we have quite
11 a strong understorey of balsam fir and probably some
12 spruce as well. So we have in this, in terms of
13 diversity on this stand, also diversity in species.
14 diversity in age. And, again, it is hard to point out
15 on the slide, but you would be able to, probably with
16 this high component of jack pine, pick out stem form
17 differences that would reflect differences in a genetic
18 diversity within the jack pine species.

19 Q. Could or would?

20 A. Which could. So in terms of actual
21 soils, I mentioned that the last slide would have a
22 high component probably of fine-textured soils, by
23 moving on to -- by the change in vegetation, I would
24 infer from this vegetation that we have a higher
25 component of coarse material now or coarser material,

1 sand.

2 This is slide No. 11. In this stand we
3 are in a pure or near pure stand of jack pine now. You
4 will notice that there is a very limited shrub layer in
5 the understory, particularly when compared to the
6 first slide that we looked at, slide 7.

7 I am sorry, what did I call that slide
8 number?

9 MR. FREIDIN: 11.

10 MR. GREENWOOD: My fault, sorry, slide 9.

11 The shrub layer that is there is
12 relatively short but it is still there and there is
13 still herbaceous growth mixed in with that shrub layer
14 which would indicate that we are on yet again a dryer
15 site than the previous slide, slightly less nutrient
16 rich and there is possibly some sort of a gravel
17 component to this soil. It could in fact be the same
18 soil type as the last one, but if you had the presence
19 of rock or gravel in the soil it could affect drainage
20 and, therefore, moisture content.

21 In terms of diversity now in the canopy,
22 there is really not species diversity, although I do
23 notice -- no, that's right, it is pure. There is a
24 minimal amount of advanced growth but there is one here
25 so we would still have some degree of age diversity in

1 this site. But you will notice that the jack pine has
2 different diameter, you have one here which is quite
3 small in diameter compared to its neighbor.

4 We also see stems that have crooks in
5 them and in fact this one has -- looks like it has
6 already died. These could be indicators of genetics
7 again, particularly when you are examining stem form.

8 In jack pine, a ripple to the stem we
9 know reflects genetics. This stem here you will notice
10 takes a little ripple here and then again here as
11 opposed to this stem which is relatively straight.
12 That would probably reflect genetics in this stand.

13 Slide No. 10. We are now still dealing
14 with pure jack pine. You will notice that there is a
15 continuous undergrowth of a low shrub, in this case it
16 is Labrador T but there is minimal herbaceous growth.

17 Something else that you will notice is
18 that the trees are much smaller. And from the crown
19 shapes I would suggest that this still is a relatively
20 mature stand as opposed to a young stand. Jack pine
21 tends to branch differently when the trees get older
22 and put on less leader growth. So the size in this
23 case, would reflect site and you could interpret
24 vegetation like this to imply quite a dry site,
25 probably low in nutrients and our organic layer is

1 probably getting quite thin here as well, a lot thinner
2 than the 10 to 15 centimetres of the first site.

3 Q. What would indicate that to you?

4 A. The dryness of the site and the
5 amount of biomass that that site is carrying in order
6 to develop an organic layer. In terms of compaction or
7 rutting, a dry site like this would not be susceptible
8 in any season.

9 Q. When you referred or used the term
10 organic layer in that answer, what are you referring
11 to?

12 A. The forest floor. In terms of
13 diversity, we are looking at single species in the
14 overstorey and very little diversity in the
15 understorey. There is no age diversity in that there
16 is not advanced growth but, again, we do have different
17 diameter jack pine, different stem forms and,
18 therefore, some reflection of genetic diversity.

19 Our last slide in this sequence, Slide
20 11, again, we are in a pure jack pine stand, there is
21 no shrub layer in the understorey, there is very little
22 herbaceous growth, if any at all. In fact, the major
23 component of the growth at the forest floor here is
24 lichen. This site is a very dry site. It would be low
25 in nutrient status. The duff layer would be quite thin

1 and, again, a site such as this would not be
2 susceptible to rutting or compaction.

3 It would be quite a coarse site, either
4 in terms of gravel or in the coarseness of the sand
5 and, therefore, water would infiltrate the site as
6 opposed to runoff and there would be quite high bearing
7 capacity or strength to this soil, a large amount of
8 macro-pores in terms of the macro-porosity that we
9 discussed.

10 And lastly, in terms of diversity again,
11 single species, no real understorey or advanced growth,
12 therefore, no age diversity but, again, you get
13 different stem diameters and would have different stem
14 form which would, in all probability, reflect genetics
15 of the species.

16 THE CHAIRMAN: Mr. Greenwood, would you
17 ever get a situation where the stem form would be the
18 same throughout a stand in any event?

19 MR. GREENWOOD: You would get stands
20 where the difference would be manifested more than
21 others, correct, but normally -- the one that I chose
22 was chosen on purpose in that jack pine tends to show
23 that variability regularly and it is quite visible. It
24 is one of the key characteristics in jack pine that is
25 controlled by genetics and is quite visible.

1 In terms of Slide No. 15, moving on to
2 the topic of erosion in a little more detail. We
3 talked about the forest floor, in this case, organic
4 layer acting to protect the soil underneath it from
5 erosion. The forest floor - this organic layer - has
6 good water infiltration and, therefore, the water moves
7 into the soil as opposed to over top and the forest
8 floor also would protect -- sorry, yes, the forest
9 floor would protect the mineral soil from the action of
10 wind.

11 We talked about the root development and
12 the root layer - root mat - that can be at the top of
13 the surface of that mineral soil and that can also
14 afford some degree of protection in holding the soil
15 together. In terms of compaction, we discussed the
16 root layer and also the protective layer of the organic
17 matter as well.

18 Slide 3. This is an area that was
19 clearcut in the summer near Chapleau using the
20 full-tree method and what I wanted to demonstrate
21 through this slide was the fact that mineral soil
22 exposure is quite limited even following full-tree
23 harvest in summer. The mineral soil shows very well in
24 this photograph, it is bright white along the roads and
25 yet within the harvested areas there is very little

1 incidence of mineral soil exposure. I can see one
2 little patch there. The rest of the, area the root mat
3 is fairly continuous.

4 Another factor, if you are concerned with
5 erosion or if you are looking for flags for it, this
6 has flat topography, the ability for water, even if
7 soil was exposed, to run off would be quite limited
8 because of a lack of slope. Another factor where the
9 soil has been exposed, you can see boulders and rocks
10 and, from experience when the exposed soil is this
11 bright in colour, bright white, we know that there is a
12 heavy sand point to it. We are looking at quite a
13 coarse material here and, therefore, very little
14 potential for erosion.

15 Slide 16. I just wanted to demonstrate
16 the fact that mineral soil exposure does take place. I
17 mentioned in my evidence that these patches are small
18 discontinuous. Here we have mineral soil exposure,
19 this lighter area where the organic material has been
20 removed, the patch is quite small and it is typical of
21 the type of exposure that can take place during a
22 summer logging operation. On many sites this would be
23 considered a positive effect in that we would be
24 attempting to create some mineral soil exposure for
25 subsequent renewal activities.

1 Slight 17 shows how windflow can create a
2 similar patch of exposed mineral soil even though you
3 can't see the patch, I think, you can see the soil that
4 is in these roots and the fact that the organic layer
5 has been uplifted. At the base of this tree would be a
6 patch -- a smaller patch as well of mineral soil which
7 had been exposed.

8 Slide 18. This is another slide showing
9 disturbance that can take place following logging.
10 Here you have disturbance of the organic layer. You
11 can see that you have areas that are fairly brown or
12 black where that organic layer has been disturbed, but
13 mineral soil exposure has not taken place. On this
14 particular site the organic layer is probably quite
15 thick.

16 I mentioned in the evidence that
17 susceptibility to erosion would normally be determined
18 by flags or cues, this was Slide 35, and we talked
19 about wind erosion and some of the cues that you might
20 look for. On a site like this, this is the lichen site
21 which you saw a few minutes ago. There is a very thin
22 organic layer over the soil. This site is very dry, so
23 I know that I'm probably on a sand texture, but the cue
24 in this area is the slight change in topography in the
25 background, right here (indicating), and there is

1 another one starting here (indicating). When you are
2 walking into an area these would stand out because most
3 of the area is quite flat. And what in fact we are
4 seeing here are sand dunes. This area has blown in the
5 past and just that one flag, that one cue, the presence
6 of a sand dune, would be an indicator to the forest
7 manager that there is a potential on this site for wind
8 erosion.

9 In determining that they were sand dunes
10 the manager would probably be considering the fact that
11 it is a dry site. you can see sand on the road. and
12 therefore. two or three of those cues confirm the fact.
13 you also could check surficial land form maps --
14 surficial geology maps I should say and these dunes may
15 be mapped. You can confirm on aerial photos where he
16 gets a larger picture how extensive this deposit is
17 and, therefore, forms prescriptions based on that.

18 This is the same site Slide No. 36 where
19 the mineral soil has been exposed. This exposure is in
20 fact on the side of the road and forms part of the road
21 and it shows that where the mineral soil is exposed,
22 the organic matter has been removed. wind will move
23 this particular texture which is a fine sand. a pure
24 fine sand. You can see that it has blown into the
25 stand in two places here. (indicating)

1 The other thing that you can see from the
2 picture is the significant effect that the organic
3 layer does have even, though in this site it is very
4 thin, in controlling erosion. Where we have wind
5 moving soil here, the boundary is still fairly distinct
6 where that organic layer is in place and movement is
7 not taking place from within that stand where the
8 organic layer is still in place.

9 Slide 37 is the first in a series of
10 three of relatively normal till sites in the boreal
11 forest. And why the comment was made that erosion is
12 not significant, particularly when we are determining
13 or examining site productivity, some of the factors
14 that would play here. I am going to take you through a
15 sequence of operations on this site. Two of the
16 pictures are from the exact location and the third
17 picture I will have to point out a few cues to show you
18 where we are. This is Slide 37 if I haven't said that.

19 Immediately following harvest on these
20 sites one of the things that is fairly prevalent is the
21 slash and organic layer across the ground and, in fact,
22 ground vegetation as well which, following harvest, is
23 acting to stabilize that site or prevent erosion.

24 This area was full-tree harvested in
25 1983. It has some topography, but it is minimal. We

1 see the presence of coarse rock, they are rather
2 angular and we get an indication again that this is
3 probably a till and, as such, has a mixture of soil
4 types but with the rock component in the soil would
5 drain fairly readily.

6 MR. FREIDIN: Q. What part of the site
7 are we looking at in this picture, the part here with
8 all the slash on it?

9 MR. GREENWOOD: A. What part -- oh, this
10 is the roadside, I am sorry. This is a skidway atf
11 roadside and the slash has been concentrated along the
12 roadside and in fact we see a rut which has been formed
13 here, where the equipment has worked at roadside and
14 the ponding which has taken place inside it.

15 This would be typical of the type of rut
16 that you would still find throughout the area of the
17 undertaking. It is small in extent.

18 Q. And the area that was full-tree
19 harvested, is that the area in the background of the
20 picture?

21 A. The boundary of the harvest in this
22 case would follow along here (indicating) just over
23 that hill. So this area in the background has not been
24 harvested -- actually this hilltop has been in the
25 background so this would be the back boundary.

1 Everything in the foreground has been full-tree
2 harvested.

3 What you should keep your eye on are
4 these two logs and this rock in the next picture.

5 Q. Mr. Greenwood, do you know or do you
6 have any information as to when that picture was taken
7 in relation to the harvest?

8 A. It was taken shortly after the
9 harvest.

10 Q. Sorry.

11 A. I just can't remember whether that
12 site was winter harvested or summer harvested, so it
13 would either be the summer after a winter harvest or
14 the following summer. So it would be six months to a
15 year following harvest.

16 Q. All right, thank you.

17 A. Slide No. 38 is immediately following
18 a prescribed burn on this site. You will notice that
19 the ground vegetation which I said has some stabilizing
20 effect has been removed. The light slash has been
21 consumed, a portion of the organic matter has been
22 consumed and the heavy slash has been dropped to the
23 ground.

24 Where the slash was quite heavy in the
25 previous photograph right here and here (indicating),

1 you will notice that we have a degree of mineral soil
2 exposure. Throughout the rest of the site the organic
3 matter is still in place and is still acting to reduce
4 the susceptibility to erosion on this site, even
5 without -- the absence of that ground vegetation.

6 This was taken within weeks of the
7 previous photo. So this site still would have low
8 potential for erosion even though there is some
9 topography change because of the organic matter still
10 being in place.

11 For the next picture you have to keep
12 your eye on this leaning tree right here (indicating)
13 that leaning tree is this leaning tree. So this is the
14 same site Slide No. -- I'm sorry, No. 40 -- sorry to
15 back up 39. This is four years after the prescribed
16 burn. The area has been site prepared mechanically
17 using the TTS disk trencher which creates a furrow in
18 the soil and then was planted with jack pine.

19 The organic mat is still in place and the
20 ground vegetation has regenerated and the jack pine is
21 quite prolific, you can see it throughout the whole
22 stand. So this site, which has gone through a series
23 of operations from harvest and treatment, has had low
24 susceptibility to erosion throughout and in this
25 condition would be of extreme -- have extremely low

1 susceptibility to erosion.

2 Now, this is Slide No. 40. I included
3 this slide just to point out the fact that excessive
4 boulders should not be construed as any indicator of
5 soil depth. Some people may look at a soil like this
6 and assume that there must be very little soil here.
7 In fact this is quite a deep till.

8 The boulders are large, they are angular,
9 they have been dumped by the ice action of the glaciers
10 retreating, dumped along with the soil and, in fact,
11 this deep soil has its organic mat still in place
12 between the boulders and as well as a vegetation -- a
13 ground vegetation in place but in this season, which
14 was spring, is not noticeable. So this site would also
15 have limited potential for erosion, primarily because
16 of the organic layer which is in place and the
17 vegetation which remains in place.

18 I also mentioned when I was discussing
19 erosion that the terrain is broken. Where we have do
20 have some topography, we have depressions next to them.
21 If, for example, erosion was taking place -- or could
22 take place on this hill it would have very limited
23 place to go. It would be deposited right at the bottom
24 and there would be very little movement across the
25 site.

1 This also is a sequence of slides. You
2 will notice the hill in the next slide. This is the
3 same site, Slide No. 40 -- I'm sorry, in this case
4 Slide 41, same site eight years later -- sorry, eight
5 years following harvest, six years after the previous
6 slide. It is in the exact location.

7 There was no treatment on this site.
8 This is natural regeneration which is taking place and
9 we can see the component of conifer in the stand as
10 well as - there is another one, there is another one -
11 as well as the birch and poplar which has regenerated
12 on the site. This site in this condition with this
13 type of growth would not be susceptible to erosion.

14 Q. And which species is the predominant
15 one in that slide?

16 A. It is pretty hard to tell. It would
17 be either poplar or birch. There is a mixture of both
18 in there.

19 Q. And would there be a reason that that
20 site wasn't treated but had been left for natural?

21 A. Primarily -- the primary reason would
22 have been the boulders. It would have been very
23 difficult to put equipment on that site and yet the
24 duff layer is fairly thick inbetween the boulders. The
25 other thing that is significant about that site, you

1 can see the lush growth and that site in fact is fairly
2 nutrient rich. If you were to go in without site
3 preparation and just attempt to plant in the duff, you
4 would have two things working against you: One would
5 be the depth of that duff, the second thing would be
6 the degree of competition that would be on the site.
7 It was originally a mixed wood site and it will
8 regenerate back to a mixed wood site.

9 Q. Thank you.

10 A. This is Slide 42 and here we have
11 what I think could be characterised as shallow soil
12 over fractured bedrock. You will notice that there are
13 pockets of soil inbetween the bedrock, outcrops, and
14 this would be representative of the sites that Mr.
15 Armson referred to as fractured bedrock but a boreal
16 example.

17 One of the things that he mentioned about
18 these sites is that there is nowhere for the soil to
19 erode to and you can see even with this hillside that
20 it would be trapped pretty quickly if it was eroding in
21 the pockets and in fact naturally has done so over
22 time.

23 This also is a sequence The next picture
24 I couldn't get this close because the area where this
25 picture was taken from was heavy to vegetation, but if

1 you keep your eye on this particular rise in the
2 bedrock and the shape of that, plus this poplar, I
3 think you will be able to identify where we are in the
4 next photograph.

5 This is photograph 43. That bedrock rise
6 starts here and goes across and drops off.

7 (indicating) and that poplar is the same one - I'll
8 maybe back up just so you can orient yourself again -
9 whoops. So this is the change in topography, and the
10 large poplar with the spruce on this hill, you can
11 see -- just the lighting is poor -- but there's the
12 poplar that lighter green colour, and the darker colour
13 is the spruce on the hill.

14 So this site -- sorry, I should say this
15 Slide 43 is seven years later. This site following
16 harvest was prescribed burned, modified mechanical site
17 preparation worked those pockets of soil and planting
18 of jack pine container stock took place following that.

19 You can see the depth of vegetation down
20 here (indicating) - this is where I took the previous
21 photo - it is quite tall now. That would reflect the
22 moisture in that depression. This poplar also shows
23 how where there is moisture you can get prolific root
24 suckering just from one or two individuals. So this
25 site has regenerated from those two or three residual

1 poplar that were left on the site. Elsewhere there is
2 the jack pine which was planted.

3 Q. Can you just go back to the previous
4 slide to see the depression that you are talking about.

5 A. The depression, you will notice down
6 in here (indicating) that there is a lot of grass and
7 green, that is quite wet, but the depression -- this
8 area where I was standing was just the other side of
9 those poplars and was also in a low area which would
10 represent the area just right in here (indicating), and
11 that bottom of the rock face would be that green area
12 that I showed in this picture.

13 The mineral soil pockets between the
14 bedrock outcrops has now been revegetated and there has
15 been limited erosion from this site.

16 Slide 44 is just a close-up of the same
17 site to show what has happened right where the bedrock
18 outcrops were. The first thing I would point out would
19 be the pocket of soil on this side where in fact you
20 can see from the angle of the bedrock that it takes a
21 dip and this area will contain the soil which did
22 support the previous forest and is in fact supporting
23 where the regeneration has taken place.

24 Now, this regeneration, as I said, was
25 six years old and it is taller than myself, so it is

1 growing quite well in those pockets. That is pretty
2 good growth if you are growing more than a foot a year
3 on what would generally be considered a fairly nutrient
4 poor site.

5 The other thing I wanted to point out in
6 this photograph is the fact that there has been moss
7 growing on this rock and that moss has been reduced
8 somewhat in that when you opened the site the heat
9 effect that I mentioned has probably dried this moss
10 out and it has been able -- it has receded somewhat off
11 the bedrock, although where it was thick and where
12 there were roots, those roots are still holding that
13 moss in place. So the change -- there has been change
14 here, but it is very slight and, in fact, as this stand
15 continues to grow and closes in it will create the
16 humidity and moisture conditions for that moss to grow
17 back onto the site.

18 I think the key here again is that the
19 trees were in the pockets before and that is where they
20 have regenerated again or where we have been able to
21 artificially regenerate them.

22 Slide No. 45 --

23 Q. You are now getting into the slide
24 which deals with -- I am sorry, okay.

25 A. One more. I mentioned in my evidence

1 and in the document in Panel 10 natural erosion and I
2 just wanted to give you some visual impression of that.
3 This is an area that is draining into Lake Abitibi
4 which is just at the southern end of the Clay Belt, in
5 fact, just as the Clay Belt starts to become more of a
6 silt clay than a clay belt.

7 Lake Abitibi is just above this
8 photograph, or just right close to where this river
9 empties into Lake Abitibi and this river which is in
10 fact draining that clay silt area carrying this load of
11 turbidity year round. It has not been affected by
12 operations, in fact there are no operations in the
13 vicinity of this river upstream that would create
14 anything like this. And Lake Abitibi is also very
15 close to this colour.

16 The rivers which are draining into Lake
17 Abitibi are draining this area and carrying this type
18 of silt load or turbidity year round. The thing that
19 is interesting here is that a river draining a
20 different type to the south, and I said this was on the
21 southern end of the Clay Belt, is not carrying the same
22 load. And so this was just to reflect some of the
23 natural erosion which can take place.

24 The next slide, Slide No. 2. We talked
25 about compaction and rutting which is now the topic I

1 would just like to give some visual impression of.

2 I made the comment that outside the Clay
3 Belt soils tend to be fairly coarse tills and,
4 therefore, aren't as susceptible to such in a real
5 sense as the Clay Belt area. This would be fairly
6 representative of some of those coarse soils. It is a
7 till again, there has been lots of boulders dumped and
8 because of its coarseness in an overall sense would be
9 low in susceptibility to compaction or rutting.

10 Now, there would be pockets within these
11 areas which would be susceptible and could in fact, if
12 equipment went through them, result in a rutted portion
13 of the site, but on the whole the site would have a low
14 susceptibility to rutting or compaction. Another
15 factor that is obvious here again is the organic matter
16 in place following harvest throughout most of the site,
17 except where roads -- these are roads and skid trails
18 within the site.

19 Slide 20 is an organic site. This area
20 has not been harvested but it demonstrates how close to
21 the surface the water table is within some of these
22 sites. This slight blue colour here is in fact a
23 reflection on top of water which is sitting right at
24 the surface.

25 It is not a particularly good slide.

1 This is a black spruce on the left-hand side growing in
2 this condition and you can see the moss, the spagnum
3 moss, clumps or patches within this site of water. It
4 is very close to the site -- very close to the surface
5 on this site.

6 The point being that a site like this
7 would have little strength, there is not a lot of
8 ground vegetation that would give strength in terms of
9 a root mat and such a site would be very susceptible to
10 rutting if equipment operated on this site in summer
11 time and had not been modified.

12 We talked about the rutting that did take
13 place. In Slide 21 you can see a situation where
14 equipment was not modified for the site. This is an
15 older area prior to FEC, prior to wide-wheeled
16 skidders, and the dark patches here are in fact water
17 throughout the whole area. So most of this area has
18 been rutted. There are still patches of moss which are
19 out of water, but a substantial amount of standing
20 water has been created on this site as a result of
21 rutting.

22 Q. And is that a picture of the
23 cut-over; is it, part of the cut-over?

24 A. That's right. This would be a
25 similar site to the previous one and after harvest,

1 after harvest in the summer situation.

2 Q. And is that condition an acceptable
3 one?

4 A. Not in my mind, no. This site would
5 create conditions very difficult for renewal on the
6 site. The areas where the ruts take place would be
7 invaded quickly by sedges and cattails which would in
8 fact start the recovery of the site but there is very
9 little micro-site here for either natural renewal or
10 artificial renewal. It would be darned hard to get
11 planters to walk across that site.

12 Slide 22. We talked about operation of
13 equipment in wet weather. Here's a site right at
14 roadside where rutting has taken place, where
15 compaction -- it is a short slope, equipment has been
16 travelling repeatedly on this section of ground.
17 Because there is a short slope here it has had to work
18 going up the hill and in fact has probably had slippage
19 of its tires which has created some of these ruts.

20 We have had organic matter partially
21 removed and mineral soil exposed. At the bottom of
22 this slope when they are coming in loaded, because of
23 the weight of that equipment hitting the bottom of the
24 slope, they have caused rutting and compaction at the
25 bottom of the slope which shows quite nicely because of

1 the water accumulation. Because of the compaction
2 water won't infiltrate into the site, so it is ponded.

3 Once you are on top of this hill the
4 organic mat is still in place and the same sort of
5 occurrence is not happening, particularly if the
6 equipment is starting to distribute itself across the
7 site.

8 Such occurrences are generally limited to
9 small areas such as this. This one is particularly
10 severe because it is at roadside where all of the
11 equipment has been channeled through, and also there
12 has been the effect of road construction here in that
13 bulldozers have removed the organic layer up to about
14 the bottom of this hill.

15 Such a site would still regenerate except
16 that it would take longer in these ruts on the
17 hillside. This area still would regenerate quite
18 satisfactorily and naturally. This area of rut would
19 take a lot longer and the area that is compacted and
20 ponded at the bottom would take longer still.

21 Slide 23. This is the same site but it
22 demonstrates the same sort of thing. This, again, was
23 at roadside, it again was an area where equipment was
24 concentrated as it was coming off this hill and out of
25 this area to roadside. It is a soft spot, you can see

1 the amount of the rock in the background. Most of this
2 site has extremely high-bearing capacity, rock holds
3 anything up.

4 But this was a soft spot at roadside
5 where equipment repeatedly travelled through and rutted
6 the soil, compacted the bottom and in fact has created
7 some ponding. Again, the severity of the occurrence is
8 quite heavy where it has occurred, but the extent of
9 the occurrence is quite small and, again, would be
10 representative of the type of rutting that you would
11 still see out on sites.

12 The vegetation in the background here is
13 two to three years old. This actual picture was taken
14 five years following harvest. There is still -- there
15 is some vegetation now coming into the bottom of those
16 ruts, you can see some sedges or grasses here and, in
17 fact, will start the process of reducing the effects of
18 that compaction and rutting.

19 Slide 24 was previously shown by Mr.
20 Oldford. Again, I just wanted to demonstrate the point
21 that a lot of the disturbance that takes place takes
22 place at roadside where equipment is manoeuvring and
23 turning and working with heavy loads. This machine is
24 in fact stirring up the organic layer and mineral soil.

25 There is some compaction taking place

1 here, water is sitting here as the machine tries to
2 work and push these logs up into a higher depth. There
3 is probably wheel spinning take place here. So we are
4 getting an effect at the immediate roadside.

5 Slide 25. The severity of that effect,
6 however, can be misinterpreted. Here we see quite
7 substantial ruts, a lot of mineral soil that's been
8 exposed and a lot of water that's sitting, but this is
9 a roadbed.

10 The harvest operations quite often take
11 place prior to the road going in or, in some
12 circumstances, the road would be frozen and the area --
13 the logs would be hauled out in winter. Equipment can
14 concentrate a lot of their movement on what will become
15 the roadbed and thereby limit disturbance to the site.

16 In this particular case you can see that
17 the organic matter is still in place on the actual site
18 and that the equipment is doing its turning and
19 manoeuvring on the roadbed.

20 Weather in both of these pictures is
21 having an significant effect, there has been
22 substantial rain and when this site was dry you would
23 not get the same effect as you are seeing now.

24 Slide No. 19. When you have susceptible
25 sites, particularly where they are large enough to

1 identify as opposed to smaller pockets, they are
2 identified and designated for the modified operations.
3 This is another organic site. It is not quite as wet
4 as the previous one that I showed where we actually saw
5 the water sitting, but in this depression you would
6 probably find some water at the bottom of that.

7 This is first in a series of three slides
8 which shows how modification of operations plus
9 identification of susceptible sites has reduced the
10 incidence of rutting in the Clay Belt area.

11 Unfortunately this is rather dark. This
12 is Slide 26. This is on the same site type as the
13 previous slide. There are still some things that we
14 can show. If in fact this had been harvested using the
15 normal narrow-tired skidder, at this point it would
16 look fairly much like that site that was severely
17 rutted.

18 You can see that the organic mat is in
19 place, there isn't water standing on this site. It was
20 harvested using a system that limits the amount of
21 travel on the site. If you see in the foreground here,
22 there is substantial advanced growth left, there are
23 also diagonal lines throughout that advanced growth.

24 On this particular site, the harvesting
25 equipment was limited to these trails, the areas

1 between were harvested using the feller-buncher that
2 was described by Mr. Oldford, the equipment did not
3 move in those areas between its rose, it reached into
4 them with the boom from both sides, and the wheeled
5 skidders that were used or modified and used, the
6 wide-tired skidders, and even though this area was
7 harvested in summer there is little site damage.

8 In the original photo - I am sorry it
9 doesn't show well - there is a little bit of rutting
10 between these two skidways where it is on the roadbed
11 again, this roadbed -- this area will not be hauled
12 until winter time and this will become the roadbed, it
13 will be frozen and these logs will be hauled out. But,
14 again, where the rutting took place, it took place as a
15 result of the equipment manoeuvring and turning at the
16 skidway at the roadside.

17 Q. Mr. Oldford, does that site represent
18 in any way the site that you described where there was
19 this careful logging method in order to protect
20 advanced regeneration?

21 MR. OLDFORD: A. Yes, that would be very
22 typical of that type of site.

23 Q. I am speaking in terms of the
24 advanced regeneration that we see there as opposed to
25 the soil?

1 A. That's correct.

2 MR. GREENWOOD: A. This photo in fact
3 was taken, Mr. Freidin, from a guide which demonstrates
4 just that, so it definitely was harvested by that
5 method.

6 Q. Okay.

7 A. This is a ground photo, Slide No. 29,
8 of the same site as a slide -- in fact it is the same
9 area as a slide two back, showing the advanced growth
10 on the ground which has been left, the skid trail which
11 has had some compaction of that moss layer but very
12 little disturbance to it and, in fact, for natural
13 seeding some compaction of that moss layer can be
14 important. So this site is largely in an undisturbed
15 condition as a result of modifying the operations in
16 the area -- first of all, identifying it accurately and
17 then modifying the operations.

18 Slide 27. I am afraid the light in the
19 room makes it difficult. This is the Ardco forwarder
20 again referred to by Mr. Oldford. You can just -- I
21 won't spend a lot on this slide, you can't see really.
22 These are the feller -- these are the bunches of trees
23 which have been left behind by the feller-buncher and
24 this machine is collecting those and moving to
25 roadside.

1 The point I wanted to make with this
2 slide again was that this particular -- the use of this
3 machine limits travel on the site by the fact that it
4 can carry what would take three skidders normally to
5 move to roadside.

6 Slide No. 28. You can see the machine a
7 little better now. It has large tires, three sets of
8 them as opposed to two on the normal skidder, two at
9 the back where the load is actually being carried. It
10 has a grapple here which has picked up two or three
11 bunches left by the feller-buncher and is carrying it
12 on the back skidding the tops.

13 What I wanted to demonstrate in this
14 slide was two things. This is on the same site as the
15 previous slide, unfortunately you couldn't see as well
16 as you should have, but there was very little in the
17 way of these dark patches which are in fact -- which is
18 some disturbances to the organic layer. The point of
19 this is that sites are not uniform even once they are
20 identified as a general site type.

21 This particular pocket that we are
22 looking at is a drainage way. Water is draining
23 laterally in this pocket on this side and on the other
24 side there is very little disturbance of the soil, but
25 this machinery, as it goes through this drainage way

1 where there is more decomposition of the organic matter
2 and less strength in that organic matter, is causing
3 some disturbance.

4 Now, the second point that is
5 demonstrated by this is how a well-trained operator can
6 limit disturbance. This particular operator has put
7 two poplars bridging this drainage way and he is using
8 those poplars as a bridge to increase his flotation
9 when he crosses the drainage way. That type of on-site
10 modification of operations is something that couldn't
11 be planned for, but it is very important in limiting
12 the amount of disturbance that can take place on a
13 site.

14 Mr. Oldford referred to the amount of
15 pressure that some of this equipment puts on the
16 ground. He talked about footprints in some of those.
17 This is an illustration of just that.

18 This is Slide No. 30 which shows an area,
19 the full width of the photograph, which a wide-tired or
20 high-floatation skidder has passed over. You can see
21 some of the imprint of its tread and a person walking
22 through that area and the depth of the imprint that the
23 person left.

24 Slide No. 31. We have spoken a lot about
25 the wide-tired equipment and the effect it has had on

1 the Clay Belt area or susceptible sites. This
2 particular piece of equipment, the feller-buncher, has
3 been equipped with wide tracks as opposed to tires
4 which also increase the ability of that piece of
5 equipment to float on top of the soil. It has created
6 compaction or an imprint within the moss. This imprint
7 is acceptable and would not create any loss in
8 productivity or ability to renew that site.

9 Slide No. 32. One thing I didn't mention
10 in the evidence was that often what is seen or
11 considered to be the results of compaction is often the
12 results of nutrient removal. In fact, I don't think I
13 have seen the results of compaction actually evidenced
14 by reduced productivity, but I have seen on landings
15 where compaction can play a part, reduced productivity
16 due to nutrient removal.

17 As was mentioned in earlier evidence,
18 landings are not used extensively in the boreal forest.
19 They were at one time, now it's mostly skidways at
20 roadside. This is an older landing which was in fact
21 planted to jack pine. The jack pine that's in front of
22 this gentleman, which is at his chest, is actually
23 bigger than some of the ones in the foreground and was
24 planted at the same time as the trees in the
25 background.

1 So on this site the organic matter and
2 the upper soil was removed and trees have survived but
3 are not growing very well, and there is also, you will
4 notice, very little presence of ground vegetation.

5 I say that this would not be as a result
6 of compaction because what we are on is a relatively
7 coarse sand here, a medium sand, and a medium sand is
8 very difficult to compact to the point where you reduce
9 that macro-porosity to the extent that you could affect
10 growth.

11 I don't know if you can see it, but there
12 are still small patches of organic layer that were left
13 and the trees actually on those sites are a little
14 taller, they respond fairly quickly.

15 Q. Through what activity would the
16 nutrient be removed from that landing?

17 A. When the landing was created it would
18 more than likely be created at the time that the road
19 was made and a bulldozer would just go in and remove
20 all of the vegetation and level the area out in order
21 to leave a spot for the skidders to operate. And so it
22 is this action of bulldozing and leveling the area that
23 would have created that landing and removed the
24 nutrients.

25 This landing, by the way, in terms of

1 extent would be probably about 40 feet long by 20 feet
2 wide. So, again, it is not a large area but the effect
3 on that area has been quite severe.

4 Q. When a skidway or a landing like that
5 was put in and you say that there would be a removal of
6 some of the soil where you have the nutrients, are you
7 referring to removal of the organic layer, the removal
8 of the mineral soil or both?

9 A. Well, there is still mineral soil
10 there, but I am referring to both. If in fact just the
11 organic layer was taken off, there is still quite a
12 large reserve of nutrients in that weathered portion of
13 the soil, again, as described in Panel 9.

14 So in a site such as this, there has been
15 a substantial amount of mineral soil removed as well as
16 the organic layer. You have gone low enough into the
17 mineral soil that whatever equipment was working there
18 has removed that portion of the mineral soil that
19 carried nutrients.

20 This is a similar example at Slide 33.
21 It is another landing, you can see the coarseness of
22 the sand in this case. The reduction in growth is not
23 as great as the previous one and this demonstrates just
24 the point that you are making, Mr. Freidin, that there
25 is still -- the depth of the removal of the mineral

1 soil on this site has been less than on the previous
2 site.

3 Slide 34. If in fact the removal of this
4 nutrient layer takes place, there are processes
5 which -- of natural recovery which will allow the site
6 to revegetate again. This is natural revegetation.
7 This has been a landing, you can see that there is
8 quite a change in vegetation here. There is a light
9 green colour across the back and again out here. That
10 is a fairly normal extent of a landing, and the
11 vegetation within that landing is a darker green in
12 colour. What you are seeing is alder growing on this
13 area which has had the nutrients removed and the normal
14 revegetation and regeneration taking place on the other
15 site.

16 Now, the significance of alder here is
17 that alder is able to obtain its source of nitrogen
18 from the air through a process called nitrogenfixation
19 and, therefore, is able to grow in this condition where
20 probably the mineral soil has not been removed to a
21 large extent, but the organic layer has been removed
22 where a large source of the nitrogen exists and,
23 therefore, these particular shrubs are getting their
24 nitrogen from the air.

25 The significance of that is that this

1 site is in a process of natural recovery now in that
2 these trees will be dropping organic leaves and debris
3 onto the floor creating a new organic layer which will
4 in fact allow other species to reinvade the site.

5 Q. And are you aware as to when that
6 picture was taken in relation to the time of harvest?

7 A. Yes, this particular site is eight
8 years following harvest.

9 MR. FREIDIN: Mr. Chairman, I think we
10 have got another six or eight photographs. I would
11 suggest that this would be a convenient time for a
12 break.

13 THE CHAIRMAN: Okay. We'll take 20
14 minutes.

15 ---Recess taken at 4:05 p.m.

16 ---Upon resuming at 4:30 p.m.

17 THE CHAIRMAN: Thank you. Be seated,
18 please.

19 MR. FREIDIN: Q. All right. Can we
20 perhaps show these slides that deal primarily with
21 diversity now, Mr. Greenwood.

22 MR. GREENWOOD: A. Yes, I think we can
23 move through these fairly quickly. This is a slide
24 taken from within the boreal forest and it was just --
25 I just wanted to utilize it to point out the mosaic

1 that I referred to when I did the diagrams.

2 You can see within this area there are
3 areas that are relatively pure in their species, there
4 is other stands which are relatively pure but to a
5 different species, and there can be quite sharp edges
6 between them, and there are also stands which have
7 mixtures of species and in fact that mixture can change
8 and create an edge between them, but not quite as
9 strong an edge. There are also -- I am sorry, Slide 46
10 I think this one is. That is all I wanted to say on
11 this slide.

12 Slide 47 were site types, in particular
13 in this case, a major land form is relatively pure
14 that can reflect itself in relatively pure vegetation.
15 This is a large glacio-fluvial deposit, it is waterlain
16 sands, sands lain by moving water south of Chapleau.
17 The area is supporting pure jack pine for virtually
18 virtually as far as the eye can see here, you can see
19 that it has been harvested partially in the background,
20 but this whole area is pure jack pine. I will outline
21 it here, so some numbers of miles.

22 In this particular case site and
23 disturbance has created a large single species or
24 limited species diversity portion of the forest. The
25 other thing that is visible on this slide is that

1 harvest, by removing mature forest and regenerating the
2 forest, is creating age diversity within the forest.

3 Slide No. 48, I was using as a good
4 example of within stand diversity. You can see within
5 this stand that there are a number of species, there
6 are in fact a number of heights of species, and you
7 would not only have species diversity in such a stand
8 you would also have age diversity this stand. Again,
9 if you look into the horizon you can see that there is
10 in fact a mosaic effect.

11 Q. Do you know what the area is - can
12 you just go back to that - the area to the right of the
13 road just before the turn?

14 A. This bare area?

15 Q. Yes.

16 A. Yes, that area is probably an area of
17 a gravel pit where material was used to build the road
18 and that also would be what -- where the water is
19 sitting at the side of the road, this is an area where
20 material has been taken and put onto roadbed to form
21 the roadbed.

22 Photograph 49. This is showing some of
23 the species diversity but now in the Great Lakes/St.
24 Lawrence Forest. Within this area you will notice that
25 there is a difference in species, however, there are

1 patches where the prevalence of a particular species
2 changes, the same on this side. So we have within
3 stand diversity we also have between stand diversity
4 also in the Great Lakes/St. Lawrence Forest.

5 I used some examples of harvesting and
6 natural regeneration and the effects on diversity.

7 One of the examples was clearcutting a poplar stand and
8 allowing the stand to regenerate naturally through root
9 suckering. This is an example of just such an area
10 where the poplar was clearcut and, in fact, what is
11 created is again a pure stand of poplar or near pure
12 stand of poplar and, as such, species diversity has
13 been maintained. The harvest itself however has
14 created an age diversity with neighbouring stands.

15 Q. That was Slide 51?

16 A. That was Slide 51, correct. This is
17 Slide 52. What I wanted to demonstrate with this slide
18 was again harvesting creating diversity of age but
19 harvesting in this sense is also maintaining a
20 relative -- I'm sorry, the species diversity is being
21 maintained over a larger area and that even within
22 areas that have been harvested and regenerated -- parts
23 that have been regenerated, there are patches of other
24 species within them.

25 In some cases this will be influenced by

1 the disturbance in that there may have been some
2 residual poplar here which root suckered or it maybe an
3 influence of a site factor where there is a change in
4 soil vegetation. If you can visualize this stand when
5 it is grown up, you will in fact see patches again of
6 diversity of species similar to what you might see in
7 the area which is not harvested where there is a patch
8 of poplar mixed in with the conifer.

9 Distributing go the harvest over an area
10 you can increase the age diversity to what would have
11 existed on this site prior to harvest resulting from a
12 natural disturbance such as fire.

13 My last slide just demonstrates - Slide
14 No. 53 - that some of the site factors are very
15 important in determining diversity. We have poplar
16 which has regenerated naturally on this site which has
17 completely overtopped what used to be a jack pine right
18 here. So this tree has succumbed to poplar competition
19 as a result of probably two things: The disturbance
20 that took place which allowed the poplar roots to
21 sucker and also a factor of site.

22 This is probably a fairly rich site. If
23 it was in fact a dry site, jack pine would more than
24 likely be able to out compete the poplar. So site
25 could have quite an effect on diversity.

1 That is my last slide.

2 MR. FREIDIN: Perhaps somebody can get
3 the lights, if somebody knows where the lights are.

4 Q. Now, in some of those photographs
5 that we looked at, Mr. Greenwood, you looked at
6 vegetation and based on the observations or the cues, I
7 think you referred to them, you interpreted what some
8 of the soil characteristics would be.

9 And just by way of summary, can you
10 indicate the parameters of soil characteristics that
11 you interpreted?

12 MR. GREENWOOD: A. I was implying from
13 the vegetation certain characteristics of the soil
14 texture and the soil moisture and through an
15 understanding of both of those some indication of
16 nutrient status of the site.

17 Q. And tell me -- one moment. How
18 confident are you in your ability to interpret cues
19 such as the ones you have indicated that are provided
20 by vegetation - I think you said there was some angular
21 rocks in some cases - how confident are you in your
22 ability to interpret those sorts of things to predict
23 soil characteristics or the parameters of soil
24 characteristics that you referred to?

25 A. Two things I think would be at play

1 there. First of all it would depend upon the degree of
2 refinement that I was trying to predict to. The second
3 thing would be where I was making the prediction.

4 On my management unit I was quite
5 confident, I knew the types of soils that were there,
6 the types of land forms that were there, I knew the
7 types of vegetation that were associated with those
8 and, therefore, I was quite comfortable in using those
9 indicators for determining the site characteristics.

10 Now, that would be as a result of the
11 fact that when I first went on to that unit and I was
12 using these indicators I would be checking, I would be
13 truthing the information that I was interpreting and,
14 therefore, learning more about how those interactions
15 took place which takes me back to the first point of
16 refinement. On my management unit, I could probably,
17 using those indicators, determine information about the
18 soil to a rather detailed level of refinement.

19 If I was taken out of my management unit
20 my confidence would be reduced somewhat, not in terms
21 of broad characteristics because the broad
22 characteristics are in fact general enough and so
23 general in fact that the terrain classification that I
24 led is for the whole boreal forest in Canada.

25 So if I knew where I was within the area

1 of the undertaking there are areas where my confidence
2 would still be fairly high.

3 I worked in northern region for a number
4 of years, I learned the land form associations there
5 with vegetation and, therefore, within that area -
6 although I could not interpret it to the level of
7 detail that I could on my management unit - it would
8 still be to more detail than say interpreting around
9 the Thunder Bay area where I have never worked.

10 Q. And would you be able to interpret
11 around say the Thunder Bay area in the broad sense?

12 A. Yes. I am sorry, in the broad sense
13 that would still apply.

14 Q. And is it necessary, in your view, to
15 be able to predict to that degree of refinement that
16 you feel you would be confident in predicting on your
17 own management unit -- is it necessary to in fact be
18 able to predict to that level of refinement in order to
19 make sound and reasonable silvicultural decisions?

20 A. No, I don't think so. There is
21 latitude within silvicultural decisions. The level of
22 refinement would allow me to possibly prescribe a
23 silvicultural prescription which would take into
24 account a factor of site that could increase growth
25 generally, however, the types of treatments that you

1 are utilizing are broad enough that the broad
2 interpretations of those indicators are enough to make
3 a silvicultural description or prescription.

4 Q. Thank you. And if you were in one of
5 these situations where you were predicting on a broad
6 range and for some reason you wanted some more
7 refinement, do you believe that there would be people
8 say on this new unit in the Thunder Bay area that you
9 had gone to who could be helpful to you in terms of
10 making more refined decisions?

11 A. Very much so. There are always staff
12 that stay on units which have that level of refinement
13 and can pass it on to a person who is just new to the
14 unit and that would be the case throughout the area of
15 the undertaking.

16 Q. Okay.

17 Q. Mr. Hynard, during the evidence I
18 believe in relation to genetic diversity and during the
19 description of the three concepts that Mr. Greenwood
20 wanted to describe to the Board, I asked you a
21 question, and during that question I think you used the
22 phrase -- you referred to high-grading and you said, I
23 think, high-grading on my unit over the last 30, 40 or
24 50 years or something to that effect.

25 Were you suggesting -- over what period

1 of time -- or is high-grading still going on in your
2 unit?

3 MR. HYNARD: A. No. If my words left
4 the impression that high-grading was occurring on my
5 unit that is a false impression, au contraire. In fact
6 our practice is more low-grading today, taking out more
7 low-grade material and keeping those trees that were
8 capable of producing quality material growing.

9 Yes, high-grading did occur on my unit,
10 it occurred since the earliest settlement days but in
11 hardwoods I think really over the period from about --
12 when truck hauls began in the 1930s, and there was more
13 hardwood cutting as a result of that, until intensive
14 management efforts began which would be in the late
15 1960s.

16 Q. Now, Mr. Greenwood, I understand that
17 before your examination-in-chief is completed that you
18 wanted to address one of the submissions that I made to
19 the Board during my opening remarks in relation to this
20 panel.

21 MR. GREENWOOD: A. Yes. You made some
22 comments concerning significance of effects and I just
23 wanted to make a few statements on that before I
24 finished.

25 In my evidence and in the evidence I led

1 today orally, it has been directed towards the effects
2 on the forest estate and, therefore, the potential
3 effects are the topics which I discussed on
4 productivity.

5 In my opinion, normal practice takes into
6 consideration that value; that is, site productivity.
7 We saw the skidder operator who had put the poplar
8 across the drainage way and that reflected a concern
9 for rutting which is in fact a concern for
10 productivity.

11 I wanted to ensure that the evidence was
12 not taken to imply that occurrences never take place,
13 they do, and some of my slides -- and through some of
14 my slides I hoped to demonstrate that. The
15 occurrences, however, are not severe or frequent or
16 large enough, in my opinion, to significantly affect
17 productivity which is the concern of the forest estate.

18 These concerns -- or these occurrences
19 however may be significant in terms of other values
20 and so when I was saying things such as erosion is not
21 significant, I am speaking from terms of on-site
22 productivity on the forest estate.

23 A lower degree of erosion, for instance
24 that which would not affect productivity, may affect
25 another value and, in my mind, this is the reason for

1 developing and using the guidelines in our management
2 planning process. So I just wanted to make that point
3 clear before we left these effects.

4 Q. And, Mr. Hynard, when you gave your
5 evidence about not having seen erosion that was of
6 concern or significant, in what respect were you giving
7 that evidence?

8 MR. HYNARD: A. I was giving it in that
9 same context.

10 Q. And, Mr. Oldford, are you able to
11 indicate whether you were also referring to it in that
12 same context?

13 MR. OLDFORD: A. In the same context.

14 MR. FREIDIN: Those are my questions for
15 Mr. Greenwood, Mr. Chairman. I understand that you
16 wanted perhaps to break at five o'clock. I think this
17 would be obviously a convenient time to break and,
18 again, I believe that we will finish tomorrow in good
19 time for people to catch the 5:05 or the flights around
20 that time.

21 THE CHAIRMAN: Okay. I think we will
22 start tomorrow at 8:30 just to be sure.

23 MR. FREIDIN: Okay.

24 THE CHAIRMAN: Thank you.

25 We will adjourn until tomorrow.

1 ---Whereupon the hearing adjourned at 4:50 p.m.,
2 to be reconvened on Wednesday, March 8th, 1989,
 commencing at 8:30 a.m.
